2. An oscill comprising a front plate; a card having a cross or cross therein, having its part on one side of the cross connected to the back of the front plate, and having its other part extending free therefrom and adapted to be turned on said cross either outwardly from, or against, said front plate; and a second card having a slot therein adapted to receive the free part of said first card, having a score or cross therein extending transversely to said slot, having its part on one side of said cross connected to the back of said front plate at each side of the free part of said first card, and having its other part extending free from said front plate and adapted when moved outwardly from the front plate to hold the free part of said first card in said slot and brace same outwardly from said front plate.

3. An oscill comprising a front plate, a back rest having one edge hinged to said front plate on a vertically-disposed axis, a brace having a slot extending longitudinally into same for a considerable distance from one edge, said brace being placed with its slot cradling said back rest and being hinged to said front plate at each side of said back rest and in such position that when the brace is folded against the front plate its slot will lie along the hinged edge of said back rest and permit same to be folded against said front plate.

700,850. MURAL BALL. JULIAN STONE, Boston, Mass.; Rachel Stone administratrix of said Julian Stone, deceased. Filed May 1, 1926. Renewed Oct. 2, 1928. Serial No. 77,768. (No model.)

Claim.—In a mural ball the combination with the hollow spherical case A, the flange a, projecting into said case, the ring 1, integral with the outer surface of said case, the ring 2, and the cord 2, connecting said rings, as specified, of the tube B, fixed at b, having collar c, and held, projecting into said case, by said flange a, enclosing said flange a, resting on said collar c, the outward-projecting tongue d, upon the inner end of said tube B, the case a, the rod-plate e, in said case, resting vibrating in said plate, and the annular groove f, in said case, enclosing the edge of said rod-plate, and said tongue, and holding the parts in position all substantially as and for the purpose set forth.

700,851. AUTOMATIC SIGNAL. RALPH L. STONE, Waterloo, Iowa. Filed July 25, 1926. Serial No. 68,571. (No model.)

Claim.—1. The combination with a frame standing above a trolley-way, a direct-clear supported thereby, a pair of movable blocks also supported by the frame and the second of which in either direction is adapted to be lifted by a passing trolley-wheel, and circuits through the direct-clear and blocks adapted to be opened and closed by the movements of the latter; of a conducting-plate supported by the frame adjacent one block, a register substantially such as herein shown and described, and a circuit leading from said plate through the actuating mechanism of the register, all as and for the purpose set forth.

2. In a register for railway-signals, the combination with the case having a box provided with a plurality of openings, the rotary dial having a plurality of rows of figures adapted to simultaneously expose the

same numerals through the different openings, a star-wheel fixed on the shaft of said dial, and a spring bearing on said wheel so as to limit the movement of said dial to an intermittent rotation; of a pair of oppositely-disposed rotatable wheels mounted on said shaft, two electromagnets in circuit with mechanisms at the ends of a track-section, devices at the latter points for sending currents alternately through said magnets as a car enters and leaves the track-section, and parts connected with the magnet-structures for turning said dial in opposite directions, all substantially as described.

3. In a register for railway-signals, the combination with a case, a rotary dial therein, and a pair of oppositely-disposed rotatable wheels on the dial-shaft; of two electromagnets located within the case and in circuit with elements at remote points, buffer-blocks located below the lower ends of said magnets and upon which their cores rest when the magnets are deenergized, and parts pivoted to said cores and having flanges adapted to rest on said blocks to hold their tips positively out of engagement with said rotatable wheels.

4. In a register for railway-signals, the combination with a case, a rotary dial therein having a star-wheel on its shaft, a tension-spring bearing on said star-wheel, and a rotatable wheel fixed on said shaft; of a pawl having an offset in its body, a block on which said offset rests when the pawl is depressed whereby its tip is held out of engagement with the rotatable wheel, and means for raising the remote end of the pawl to lift its offset off the block and engage it tip with said rotatable wheel.

700,852. INTERCONVERTIBLE BED OR COUCH. DAVID G. GOUCH, New York, N. Y. Filed Jan. 23, 1926. Serial No. 8,462. (No model.)

Claim.—1. An interconvertible bed or couch, comprising a main frame, side frames, an independent depressible foot device for each side frame, and independent connections between said foot device and said side frames, whereby each side frame may be elevated independently of the other, the said independent foot device being adjacent to each other and movable in parallel planes, whereby they may be simultaneously operated when desired.

2. An interconvertible bed or couch, comprising and standards, a main frame, side frames adapted to be raised to horizontal position, lever mechanisms for operating said side frames and an independent foot device for actuating the lever mechanism of each of the side frames, said foot devices being projected through parallel slots in one of the said end standards, and being arranged whereby they may be engaged simultaneously by the foot.

700,853. COUCH-BED. DAVID G. GOUCH, New York, N. Y. Filed Feb. 19, 1926. Serial No. 4,345. (No model.)

Claim.—1. A couch-bed comprising a main frame and end standards each having legs bent outwardly at their lower ends and connected by a cross-brace, said legs and brace of each standard being formed from a single strip of angle-iron, presenting a flat horizontal web connecting the lower ends of the legs.

2. A couch-bed comprising and standards each formed of angle-iron bent to constitute two legs and a lower cross-brace presenting a flat horizontal web connecting the lower ends of the legs, on end bar across and

connecting the upper ends of said legs of each standard, longitudinal side bars connecting said standards, braces connecting said side bars with the lower portions of said end standards and braces connecting said side bars with the said end bar.

3. A couch-bed consisting of angle-iron end bars; an end standard for each end bar, each standard consisting of a lower angle-iron cross-bar bent to form legs which curve inward and upward and are secured at their ends to the said end cross-bar, said cross-bar presenting a flat horizontal web connecting the lower ends of the legs, side bars connecting the legs of the standards, and a spring mattress or fabric secured directly to end standard between the said end bar.

4. A couch-bed consisting of a main frame comprising angle-iron end bars, angle-iron legs bolted directly to said end bars and suitably braced together by a lower cross-bar integral therewith, and having a flat horizontal web, and side bars connecting the said legs; a side frame consisting of end bars pivoted to the ends of the first-mentioned side bars, and a side bar connecting the outer ends of the pivoted end bars; a spring mattress or fabric stretched between and connected directly to the end bars of the main and the side frames; and mechanism for supporting said side frame when raised to horizontal position.

5. A couch-bed comprising a main frame, swinging side frames, depressible foot devices for raising said side frames independently of each other, means for holding said side frames raised, and independent mechanisms for permitting the lowering of said side frames, independently of each other, the said foot devices being adjacent to each other and movable in parallel planes, whereby they may be simultaneously operated when desired.

6. A couch-bed comprising a main frame, swinging side frames, depressible foot devices for raising said side frames independently of each other, the said foot devices being adjacent to each other and movable in parallel planes, whereby they may be simultaneously operated when desired, and independent latch mechanism for said side frames, whereby one side frame may be dropped independently of the other.

7. A couch-bed comprising a main frame, a swinging side frame, lever mechanisms at each end of the bed for supporting the side frame when elevated, pivoted latches at the ends of the bed for engaging said lever mechanisms, said latches each having a tapering depending and portion and a socket, said sockets being oppositely disposed, and means connecting the upper end of one latch with the lower end of the other, whereby they may be simultaneously operated.

700,854. TANK-BRATHE. JOEL STAMM, Bern, Korea. Filed May 28, 1921. Serial No. 61,667. (No model.)

Claim.—The herein-described tank-brathe comprising a shallow hollow base having an opening in its top and a rim extended vertically from the said opening, a hollow body having its lower end fitted within the said rim and covered thereto and formed with an inner flange, a ring removable through the hollow body and having an outer flange at its upper end to rest upon the inner flange at the lower end of the hollow body

and hold the ring suspended within the upper portion of the hollow base, an outlet-pipe connected to the top of the base at one side of the hollow body, and a cover fitted to the upper end of the hollow body and having damper-controlled openings, substantially as described.

700,855. CASTING DENTAL PLATE. WILLARD STRIMMER, Chicago, Ill. Filed June 12, 1901. Serial No. 64,481. (No model.)

Claim.—1. In a mold for casting metal, a flask provided with a neck and containing an investment the neck approximately as large as the flask, in horizontal measurement, and a pouring-channel in the neck flaring at the top and tapering thence in both diameters through the neck and into the investment in the flask to the upper edge of the matrix.

2. In a mold for casting metal, a flask provided with a neck and containing an investment, and a wide pouring-channel tapering in both of its diameters, through the neck and into the investment in the flask, to the upper edge of the matrix as herein set forth.

3. A device for casting metal consisting in a flask with a plane top made in two members means for binding said members together, vertical ribs at the top of each member, an investment in said flask containing the mold, and a tapering channel leading thence, a neck with a plane bottom and approximately the same size as the flask in horizontal measurement, recesses in the neck to engage the said ribs on the flask and a pouring-channel through the neck gradually tapering in both of its diameters to the channel in the investment in said flask, substantially as herein set forth.

700,856. GAME APPARATUS. WARREN G. TALBOT, Providence, R. I. Filed Nov. 2, 1901. Serial No. 59,998. (No model.)

Claim.—The game-covered board A herein described, the same comprising the square base a provided with a center or median line c and having a series of stations d located equidistantly from the center of the base and arranged around the outer edge thereof, and further having the stations arranged with respect to said center line whereby the latter equally divides the series of stations, and a movable disk f adapted to enter or cover the said stations upon properly manipulating the box, substantially as described.

700,857. INCANDESCENT GAS-BURNER. IRVING R. TAYLOR, Buffalo, N. Y. Filed Jan. 2, 1902. Serial No. 59,998. (No model.)

Claim.—1. In a burner of the type described, the combination with the exteriorly-threaded supply-tube, and the nipple; of the mixing-chamber whose bottom is slightly dished and provided with a central opening, and a transverse strip within and connected with said bottom, passing

across and narrower than said opening, and provided with a threaded hole concentric with each opening and adapted to engage the supply-tube.

2. In a burner of the type described, the combination with the supply-tube and nipple; of a mixing-chamber comprising two members, perforated lugs on the lower member, fingers on the upper member provided with perforations adapted to align with those in said lugs, and pins entering the aligned perforations with their lower ends standing against said supply-tube.

3. In a burner of the type described, a mixing-chamber comprising two members, perforated lugs on the lower member, spaced fingers on the upper member two of which are provided with perforations adapted to align with those in said lugs, a damper surrounding and adapted to turn around said fingers and having similar diametrically opposite perforations, and pins insertible through the aligned perforations in the two members and adapted to stand within the perforations of the two members.

4. In a burner of the type described, a mixing-chamber comprising two members, perforated lugs on the lower member, fingers on the upper member provided with perforations adapted to align with those in said lugs, pins entering the aligned perforations, and removable means for holding said pins with their heads flush with the outer face of the upper member.

5. In a burner of the type described, the combination with the supply-tube and nipple; of a mixing-chamber comprising two members, perforated lugs on the lower member, spaced fingers on the upper member two of which are provided with perforations adapted to align with those in said lugs, a damper surrounding said fingers and having similar diametrically opposite perforations, and pins entering the aligned perforations with their lower ends standing against said supply-tube.

6. In a burner of the type described, the combination with the mixing-chamber having air-inlet openings in its sides and also in its bottom, and a damper for regulating the size of the side openings; of a strip passing across but narrower than the bottom opening, a source of gas-supply entering the bottom of said chamber and passing through said strip, a long cylindrical mixing-flue rising from its top and of smaller diameter than said chamber, and the burner-head at the upper end of said flue.

7. In a burner of the type described, the combination with the gas-supply, the mixing-flue, and the burner-head; of the mixing-chamber comprising a dished lower member and a dome-shaped upper member into the space of which later said flue is threaded, a transverse strip integral with and extending across the interior of the lower member which latter is provided with a hole of greater diameter than the width of the strip and remaining always open to admit some air, lugs at the extremities of this strip, spaced fingers depending from the upper member and adapted to pass outside the lugs, means for adjustably connecting the latter with two of said fingers, and a damper for adjusting the size of the openings between said fingers.

8. In a burner of the type described, the combination with the burner-head, the mixing-flue, and the mixing-chamber comprising upper and lower

members with side openings and a damper therefor; of a transverse strip integral with and extending across the interior of the lower member which latter is provided with a hole of greater diameter than the width of the strip and remaining always open to admit some air, the gas-supply passing through said strip, and means at the extremities of the latter for detachably connecting the members of the mixing-chamber.

9. In a burner of the type described, the combination with the mixing-chamber having adjustable air-inlet openings, and a source of gas-supply; of a mixing-flue rising from said chamber and having notches in its upper extremity, and a burner-head comprising a solid casing having at its lower end a cylindrical bore surrounding and larger than the flue and at its upper end a tapered base adapted to rest at the extremity of the flue whereby additional air is admitted into the flue radially through said notches.

10. In a burner of the type described, the combination with the mixing-chamber having adjustable air-inlet openings, and a source of gas-supply; of a mixing-flue rising from said chamber and having notches in its upper extremity, and a burner-head having a gallery at its lower end, and an interior bore larger at its lower end than the exterior of said flue, thence tapering inward so as to rest at the upper end of the flue whereby additional air is admitted through said notches, then shouldered, and terminating at its upper end in a smaller bore.

700,858. AIR PURIFYING AND COOLING APPARATUS. RICHARD H. THOMAS, Chicago, Ill. Filed Apr. 18, 1901. Serial No. 56,097. (No model.)

Claim.—1. An air washing and drying apparatus comprising a chamber having a tank communicating therewith and adapted to hold a liquid, rollers disposed to dip into the tank, rollers disposed at the top of the chamber, rollers disposed between the first and second series of rollers, a wringer coating with one of the rollers, an absorbent material extending transversely throughout the width of the chamber and passed over the rollers to move in places at angles to the liquid-level of the tank, and air-chutes disposed to convey air to and from the chamber for passage through the absorbent material, whereby the air will be first washed and then dried.

2. A device for washing and drying air comprising a chamber having a liquid-holding tank, and absorbent material extending throughout the width of the chamber, guide-rollers disposed to direct the material first through the tank and then backwardly and forwardly thereabove, and a wringer coating with one of the rollers, said chamber having air inlet and outlet openings to permit of passage of air to through and from the absorbent material, whereby it may be first washed and then dried.

700,859. AIR PURIFYING AND COOLING APPARATUS. RICHARD H. THOMAS, Chicago, Ill. Filed May 21, 1901. Serial No. 61,366. (No model.)

Claim.—1. An air purifier and cooler comprising a chute having alternating series of baffle-plates, the plates of one series having troughs at their upper edges and the plates of the other series having troughs at their lower edges, said series being disposed one behind another and dis-

ing longitudinally in the same direction, and means for discharging a wall of water transversely of the chute and in advance of the plates.

2. An air purifier and cooler comprising a chute having a casing at one side and on the interior thereof, alternating series of baffle-plates projected into the casing, the plates of one series having troughs at their upper edges and the plates of the other series having troughs at their lower edges, said series being disposed one behind another and discharging longitudinally in the same direction, means for discharging a wall of water in advance of the plates, and means for forcing the casing of water.

700,860. VACUUM APPARATUS FOR BOILING BRINE. RICHARD H. THOMAS, Chicago, Ill. Filed July 13, 1900. Serial No. 52,680. (No model.)

Claim.—1. In apparatus for boiling brine the combination with a pan provided at its lower end with a tubular extension, a brine vessel open to the atmosphere and arranged below said extension to receive the same, means for heating the pan and means for creating a vacuum in the pan, of an air-cock connected with the vacuum-space of the pan, a manometer in communication with said space, two normally open circuits for operating said cock, a pair of contacts under the control of said manometer for completing one circuit when the vacuum in the pan is caused to rise above the normal degree, another pair of contacts under the control of said manometer for closing the other circuit when the vacuum in the pan is caused to fall below the normal degree, and a source of electricity connected with said circuits, substantially as and for the purpose described.

2. In apparatus for boiling brine the combination with a brine vessel open to the atmosphere, a pan provided at its lower end with a tubular extension located in said vessel, means for heating the pan and means for creating a vacuum in the latter, of an air-cock communicating with the top part of the pan, a solenoid for opening and a solenoid for closing said cock, a source of electricity, connection between said solenoids and source of electricity, a movable contact placed in said connection and controlled by the quicksilver of a manometer communicating with the pan, and stationary contacts arranged in said connection for cooperation with said movable contact to alternately close the circuits of said solenoids, substantially as and for the purpose described.

3. In apparatus for boiling brine the combination with a brine vessel open to the atmosphere, a pan provided at its lower end with a tubular extension located in said vessel, means for heating the pan and means for creating a vacuum in the latter, of an air-cock communicating with the top part of the pan, a solenoid for opening and a solenoid for closing said cock, a source of electricity connected at one pole to both of the said solenoids, a tube communicating with the vacuum-space of the pan, a vessel containing quicksilver and arranged to receive the lower end of said tube, an electric contact arranged in said tube and connected with one of the solenoids, another electric contact arranged in said vessel and connected with the other solenoid, and a third electric contact so arranged as to permanently dip into the quicksilver of said vessel and connected with the other pole of said source of electricity, substantially as and for the purpose described.

700,861. TOY. HENRY P. WALKER, Fort Madison, Iowa. Filed Feb. 5, 1902. Serial No. 52,708. (No model.)

Claim.—1. A toy comprising a base, an upright post carried thereby, a rotatable platform supported by the post and forming a rotational driving-surface, a driving-shaft having a wheel-handle forming a counter-

weight, means for supporting said shaft, a disk secured to the shaft and adapted to frictional contact with the under side of the reversible platform, said disk having a portion of its periphery flattened or cut away at a point diametrically opposite to said crank-handle, the superior weight of that half of the disk opposite the cut-away portion, together with the weight of the crank-handle curving on a counterbalance to normally maintain the disk out of contact with the platform.

2. A toy comprising a base, a pair of strips of metal bent into loop form and secured to said base, a driving-shaft supported by said strips, an upright post 11 having its lower end adapted in a base-socket and partly supported by one of said strips, a reversible platform having a central opening for the passage of the said post, an upper strip carried by the platform and having a socket for the reception of said post, and a driving-disk carried by the driving-shaft and adapted for contact with the under side of said reversible platform.

700,862. CONVERTIBLE HARROW AND LAND-ROLLER. HENRY L. WALKER, Ripley Station, Ky., assignor of one-half to John W. Tamm, Ripley Station, Ky. Filed July 20, 1901. Serial No. 70,150 (No model.)

Claim.—1. The combination of a flexible body comprising a series of bars and flexible connections between them, said body being disposed in cylindrical form, and heads in said cylindrically-formed body, said heads having projecting spurs and the bars of said flexible body having openings to receive said spurs, substantially as described.

2. In a convertible harrow and land-roller, a flexible body for the purpose set forth, comprising a series of bars disposed side by side, and provided with transverse aligned openings, a flexible element extending through said openings and connecting said bars together, and flexible connecting elements, on one side of said bars and connecting them together, substantially as described.

700,863. DOOR FOR MAIL-WAGGON. WILLIAM E. WAGGONER, South Bend, Ind. Filed Sept. 20, 1901. Serial No. 73,561. (No model.)

Claim.—1. In a mail-wagon, the combination with the door or doors having an opening formed therein, of a vertically-swinging door hinged at its bottom to the edge of said opening by a spring-hinge to normally hold the supplemental door closed, and means to lock the supplemental door, substantially as specified.

2. In a mail-wagon, the combination with the door or doors having

an opening formed therein, of a vertically-swinging sub-door hinged to the edge of the opening in the door proper, a spring-hinge to normally hold the sub-door closed, said sub-door arranged to be held at right angles to the door to provide a shelf within the mail-wagon, substantially as described.

700,864. DETACHABLE ALARM FOR KETTLES. BURNHAM WHITTIER, Boston, Mass., assignor of one-half to Louis Jacobson, Cambridge, Mass. Filed Mar. 26, 1902. Serial No. 90,593. (No model.)

Claim.—1. As a new article of manufacture, a detachable alarm for kettles consisting of a tubular stem having a discoidal whistle attached to one end thereof, a support having a post for the whistle in one end and a hole through which said stem passes, said stem projecting beyond the opposite end of said support, the end of the projecting portion being screw-threaded and a clamping-nut on said screw-threaded end, substantially as described.

2. As a new article of manufacture, a detachable alarm for kettles comprising a pair of centrally-perforated concave disks which are oppositely arranged and connected at their edges to form a chamber, a support having a post in one end in which one of said disks is located, and a hole which passes through it from end to end, a tube having a circumferentially-flanged end, said tube extending through the hole of said support and the perforation of the adjacent disk, the flanged end of said disk being located in said chamber and its opposite end projecting beyond said support and being screw-threaded, and a nut on said threaded end, substantially as described.

3. As a new article of manufacture, a detachable alarm for kettles comprising a pair of centrally-perforated concave disks which are oppositely arranged and connected at their edges to form a chamber, one of said disks having an annular lip surrounding its perforation, which projects into said chamber, a support having a post in one end in which said latter disk is located and a hole which passes through it from end to end, a tube having a circumferentially-flanged end, said tube extending through the hole of said support and the perforation of the adjacent disk, the flanged end being located within the chamber and its opposite end projecting beyond the support and being screw-threaded, and a nut on said threaded end, substantially as described.

700,865. CUTTING-TOOL. SAMUEL WELSH and JOHN ARMSTRONG, Chicago, Ill., assignors to Armstrong Bros. Tool Co., a Corporation of Illinois. Filed Oct. 1, 1901. Serial No. 77,903. (No model.)

Claim.—1. A thread-cutting tool having a curved and beveled edge of uniform width, a pivot to which each edge is concentric and being located between the cutting edge and the center of the circle of which each edge is an arc, and a cutting-flare radial to the pivot.

2. A thread-cutting tool having a pivot-aperture, and a cutting-flare and a bearing-flare relatively on opposite sides of each aperture, the periphery of the cutter extending back from the cutting-flare on an arc-struck from a center more remote than the pivot-aperture and the bearing-flare extending in the opposite direction from the cutting-flare approximately on a concave curve relatively to the pivot-aperture.

3. In a thread-cutting tool, in combination, a stock, a cutter pivotally secured to the stock and having a cutting-flare radial to the pivot, a portion of the periphery of the cutter being the cutting edge and extending backwardly from the cutting-flare and a portion of the periphery of the cutter being a bearing-flare, each two portions being on opposite sides of the pivot and concentric therewith, the said pivot being located between the cutting edge and the center of the circle of which each edge is an arc and the bearing-flare gradually approaching the pivot from its end nearest the rearward end of the cutting edge, and an adjustable member carried by the stock and engaging the bearing-flare.

4. A thread-cutting tool provided with a pivot-aperture and a cutting-flare radial to the pivot-aperture, a portion of the periphery of the tool being a cutting edge and a portion thereof being a bearing-flare, both

of each peripheral portion being concentric to the pivot-aperture and the line of the cutting edge extending from the cutting-flare and gradually approaching the pivot-aperture as it recedes from the cutting-flare.

700,866. DARNING-LAMP. EDNA R. WHITE, Stillman Valley, Ill. Filed July 31, 1902. Serial No. 72,044. (No model.)

Claim.—1. In a darning apparatus, in combination, a frame for holding the fabric to be darned; two series of harness-loops extending transversely across the darning-frame near the middle thereof, the opening in each of said loops extending substantially at right angles to the line of the series to which the loop belongs, said loops being normally substantially closed at all sides; a pivotal support for each of said series of harness-loops; and means for applying power to move said series in opposite directions upon their said pivots.

2. In a darning apparatus, in combination, a frame for holding the fabric to be darned; two series of harness-loops, the opening in each of said loops extending substantially at right angles to the line of the series to which the loop belongs, said series extending transversely across the darning-frame near the middle thereof, said loops being normally substantially closed at all sides; a pivotal support for each of said loop series; and a thumb-piece for each series, for moving the same.

3. In a darning apparatus, in combination, a frame for holding the fabric to be darned; two tilting plates at opposite ends of said frame, which plates face each other; a series of loops on each of said plates on the adjacent edges thereof, which loops are in eye form, normally substantially closed at all sides; and a thumb-piece for each tilting plate adapted to move the same.

4. In a darning apparatus, in combination, a frame for holding the fabric to be darned; two series of harness-loops, the opening in each of said loops extending substantially at right angles to the line of the series to which the loop belongs, said series extending transversely across the darning-frame near the middle thereof, said loops being normally substantially closed at all sides; a pivotal support on the frame on opposite sides thereof, for each of said series of loops; and means for applying power to move said series in opposite directions upon their said pivots.

5. In a darning apparatus, in combination, an elliptical frame for holding the fabric to be darned; two series of harness-loops, said loops being in eye form, normally substantially closed at all sides; a tilting plate for supporting each of said series of loops; and a pivot and a thumb-piece for each of said plates.

6. In a darning apparatus, in combination, a frame for holding the fabric to be darned; two tilting plates pivotally mounted on opposite sides of said frame; a series of harness-loops on each of the adjacent edges of said plates, said loops being in eye form, normally substantially closed at all sides, the loops of one series alternating in position with those of the other series; and a thumb-piece for each of said tilting plates, for moving said plate.

7. In a darning apparatus, in combination, a frame for holding the fabric to be darned; two tilting plates therefor, which plates face each other, each of which is provided with an upturned rear end, and is pivotally mounted near one end of said frame; and a series of harness-loops fixed upon the front edge of said tilting plates, the loops of one series alternating in position with the adjacent loops of the other series.

700,867. DEVICE FOR HOLDING REMOVABLE LEAVES. RALPH C. WHITMAN, Los Angeles, Cal. Filed Jan. 24, 1902. Serial No. 81,570. (No model.)

Claim.—1. The device for holding or binding together other the form or manner of a book, leaves or removable sheets of paper, said device consisting of an expandable back portion with flat top portions where-in one or more rings each having internal teeth are carried joints for engaging the rings to be opened and closed and a shaft or bar with a handle

the capable of having both a sliding and rotating movement imparted to it, said shaft having steps thereon and pistons operating in internal teeth or toothed recesses in each of the one or more opening and closing rings, the said device also containing toggle-jointed levers connected pivotally to the top portions of the back, said toggle-jointed levers being operated by the screw-like movable bar and handle, one of said toggle-jointed levers having a stud engaging with a grooved roller on said shaft or bar, for opening and closing said rings, the grooved roller also the springs connecting the upper parts of the back, all operating in the manner and for the purposes substantially as hereinbefore described.

2. The combination consisting of the flexible back, the flat top portions of said back the one or more internally-toothed opening and closing rotatably-mounted rings held in said back, the sliding and rotatable bar and handle, the steps on said bar, the pistons on said bar, the grooved roller on said bar, the toggle-jointed levers and stud operated by said bar and grooved roller, the bearings for said bar and toothed pistons, the covers or sides of the device and the flexible outer portions of said covers, also the spiral springs, all operating together in the manner and for the purposes substantially as hereinbefore described.

3. The combination consisting of the flexible back, one or more jointed opening and closing rotatably-mounted toothed rings held in said back, the sliding and rotatable bar and handle, the steps on said bar, the pistons on said bar, the grooved roller on said bar, the toggle-jointed levers and stud operated by said bar and grooved roller, the bearings for said bar and pistons, the opening and closing rotatably-mounted rings, the covers or sides of the device and the flexible outer portions of said covers, all operating together in the manner and for the purposes substantially as hereinbefore described.

700,868. DRIVING MECHANISM. OTTO WELTMEYER, Brooklyn, N. Y. Filed Apr. 17, 1901. Serial No. 60,199. (No model.)

Claim.—In mechanism of the class described, a driving-shaft provided with a spring-key, a driving-wheel having key-seat cavities formed therein for the reception of the screw-like key, a clutch-collar rabbeted to form a keyway, a stationary segment-plate secured to the frame of the machine, a second segment-plate secured to the treadle, joined to the stationary segment at one end, and provided with an opening at the junction of the opposite ends for the passage of the key, the outlet of said passage having means for covering the same, substantially as set forth.

700,869. ELECTRODE. KARL A. WILKE, Chicago, near Hamburg, Germany. Filed Sept. 22, 1900. Serial No. 30,600. (No model.)

Claim.—1. A flat electrode for secondary batteries comprising a carrier formed of a suitable material, provided with a substantially helical groove and an active material in said groove, substantially as and for the purpose set forth.

2. An electrode-carrier composed of a suitable material and provided with a plurality of substantially helical ribs, and lateral projections formed on said ribs at opposite sides of the electrode, substantially as and for the purpose set forth.

3. An electrode-carrier composed of a suitable material and provided with a plurality of ribs arranged to form a multiplex helix, and lateral projections at opposite sides of the electrode at each turn of the helix, substantially as and for the purpose set forth.

4. A flat electrode-carrier composed of a suitable material and having inclined ribs arranged in the form of a multiplex helix, substantially as and for the purpose set forth.

5. An electrode-carrier composed of ribs of a suitable material inclined in opposite directions on opposite sides of the electrode, connected at their crossing and lateral ends on each inclined rib, substantially as and for the purpose set forth.

6. An electrode-carrier composed of ribs of a suitable material inclined in opposite directions on opposite sides of the carrier, a plate between the series of ribs, said ribs and plate connected at their crossing-points and lateral ends on each inclined rib, substantially as and for the purpose set forth.

7. An electrode-carrier comprising a plate, inclined ribs on one side thereof inclined in one direction and similar ribs on the opposite side inclined in an opposite direction, and lateral ends on each inclined rib, the plate being cut away between said ends, substantially as and for the purpose set forth.

700,870. SAWHILL AND PLAMER. EDWARD E. WILLARD, Edgway, Pa. Filed July 2, 1897. Serial No. 643,374. (No model.)

Claim.—1. A rotary log-champ consisting of a cylinder journaled to rotate in a suitable bearing, a flange formed on or firmly attached to the inner end of the cylinder and provided with teeth designed to secure and contain one end of a log when it is pressed against them, while the other end of the log is supported by any suitable center on which it may rotate, and so constructed that the log may at the same time be pressed and firmly held against the toothed flange of the cylinder; at the outer end of the journaled cylinder a washer recessed to receive the projecting end of the cylinder and having a hole in its center through which passes the shaft of a clamp-curve which is fitted to work in a threaded hole extending through the cylinder, the screw-shaft being provided with a collar formed on or firmly attached to the shaft outside of the washer, and designed to press against the washer and draw it toward the cylinder, in the manner and for the purpose described.

2. A rotary log-champ consisting of a flanged cylinder journaled to rotate in a suitable bearing, a threaded hole in the center of the cylinder through which a clamp-curve with a corresponding thread passes; the screw having journaled to its inner end a disk provided with teeth which may, by rotating the screw, be pressed firmly against and into one end of a log to secure and contain it, while the other end is supported by any suitable center on which it may rotate, and by which it may be pressed and held against the teeth of the disk; a set-screw being fitted to press against the journaled cylinder to prevent it from rotating when so desired, as shown and described.

3. A rotary log-champ consisting of a flanged cylinder journaled to rotate in a suitable bearing, a threaded hole in the center of the cylinder through which a clamp-curve with a corresponding thread passes and works, the clamp-curve rotated by means of a hand-wheel attached to its outer end and having journaled to its inner end a disk provided with strong teeth which may, by rotating the screw, be pressed firmly against and into the end of a log, a set-screw passing through a threaded hole in the bearing and pressing against the cylinder to prevent the cylinder from rotating when so desired; and alternatively and in combination with the same, another rotary log-champ consisting of a cylinder journaled to rotate in a suitable bearing, a flange formed on, or firmly attached to, the inner end of the cylinder and provided with teeth designed to secure and contain one end of a log when it is pressed against them; at the outer end of the cylinder, a washer recessed and constructed to slide a short distance along the journaled part, a hole through its center in which a clamp-curve freely rotates and retains it in place; the journaled cylinder having a threaded hole through its center in which the clamp-curve, actuated by a hand-wheel at its outer end and provided with a corresponding thread, passes and works; the clamp-curve also provided with a collar firmly attached and designed to press against the washer and draw it toward the cylinder when the clamp-curve is rotated and in this manner to clamp the cylinder and prevent it from rotating when so desired, substantially as shown and described.

4. A rotary log-champ consisting of a longitudinal bar having firmly fastened near its ends flanged cylinders fitted to bearings in which they may freely rotate; at the outer end of one of the cylinders a washer, recessed and constructed to slide a short distance along the journaled part, a hole through its center in which a clamp-curve freely rotates; the screw working in a threaded hole through the center of the cylinder in draw the washer toward the cylinder and prevent the cylinder from rotating when so desired; a threaded hole through the other journaled cylinder in which a clamp-curve works having a disk at its inner end in which it is journaled to rotate, the disk having a hole through which the longitudinal bar is passed on which it slides when the screw is rotated, substantially as shown and described.

700,871. RUBBER-TIRE-CUTTING MACHINE. JOHN E. WILKINS, ALBANY, N.Y. Filed Dec. 12, 1899. Serial No. 643,375. (No model.)

Claim.—1. In a rubber-tire-cutting machine, the combination of arms mounted to rock on the axle line of the wheel to be fitted, and bearing longitudinally-adjustable wire-gripping devices, at their free ends, and means for drawing said free ends bearing said devices toward each other, substantially as shown and described.

2. In a rubber-tire-cutting machine, the combination of arms mounted to rock on the axle line of the wheel to be fitted, and bearing longitudinally-adjustable wire-gripping devices, at their free ends, and means for drawing said free ends bearing said devices toward each other, substantially as shown and described.

3. In a rubber-tire-cutting machine, the combination of arms mounted to rock on the axle line of the wheel to be fitted, bearing wire-gripping devices on their free ends, means for drawing said free ends toward each other, and independently-acting windlasses to severally draw said wires, substantially as shown and described.

4. In a rubber-tire-cutting machine, the combination of two arms mounted to rock on the axle line of the wheel to be fitted, bearing longitudinally-adjustable wire-gripping devices on their free ends, means for drawing said free ends toward each other, and independently-acting windlasses to severally draw said wires, substantially as shown and described.

5. In a rubber-tire-cutting machine, the combination of two oppositely-disposed arms mounted to rock on the axle line of the wheel to be fitted, provided in their outer portions with ways, radial to their line of movement, and bearing wire-gripping devices longitudinally adjustable therein, and means for causing said arms to approach each other, substantially as shown and described.

700,872. SUSPENDED-BUCKLE. HARRY E. WILSON, Lockhaven, Pa. Filed Oct. 20, 1901. Serial No. 79,985. (No model.)

Claim.—1. In suspension, the combination with the webbing band doubled upon itself and having a terminal loop, one portion of which is located against the adjacent face of the main band of webbing, of a buckle comprising a base-frame that is located wholly within the terminal loop and is open to permit the opposite portions of said terminal loop being pressed together, a cross-bar joined to the opposite edges of the base and extending across the outer face of one side of the loop and the main band of webbing, and a locking-tongue pivoted upon the cross-bar and having an offset tooth that projects into the open portion of the frame and presses the band of webbing and the adjacent portion of the terminal loop through the base and against the opposite portion of said terminal loop whereby a yielding cushion is formed for the webbing band.

2. In a buckle, the combination with a base, of a pivot-bar extending across and spaced from the base, and a tongue pivoted upon the bar and comprising a looped wire coiled about said bar, the terminals of said tongue being intended to constitute teeth that meet with the base.

3. In a buckle of the class described, the combination with a frame having a contracted neck, and a pivot-bar extending transversely across the neck, of a tongue pivoted upon the bar and comprising a looped wire, the terminals of which constitute a pair of web-engaging teeth that are located on opposite sides of the neck.

4. In a buckle of the class described, a frame having a contracted neck provided with outstanding arms, a cross-bar connecting the terminals of the arms and spaced therefrom, and a tongue pivoted upon the cross-bar and comprising a looped wire, the terminals of which are coiled about the cross-bar and the ends being bent to form teeth that are located on opposite sides of the neck and meet with the outstanding arms thereof.

5. In a buckle of the class described, a wire frame comprising a base having a neck and oppositely-extending outstanding arms provided with offset portions constituting teeth, the terminals of said arms being con-

structed by a cross-bar which extends transversely of and is spaced from the neck, and a tongue pivoted upon the cross-bar and comprising a looped wire having its end portions coiled about said bar and its terminals bent to form teeth that are movable into and out of the said neck in the axis of the frame.

6. In a buckle of the class described, the combination with the frame having a cross-bar provided with an intermediate offset leg, of a tongue pivoted upon the cross-bar and comprising a looped wire, the end portions of which are coiled about said bar and its terminals being bent to form holding-teeth, said terminals being bent to form holding-teeth, said terminals being bent to form holding-teeth, said terminals being bent to form holding-teeth.

7. In a buckle of the class described, the combination with a frame having a cross-bar, of a tongue pivoted upon the cross-bar and comprising a looped wire, the end portions of which are coiled about said bar and the terminals being bent to form holding-teeth, said terminals being doubled upon themselves to form blunt engaging ends.

8. In suspension, the combination with the webbing band doubled upon itself and having a terminal loop, one portion of which is located against the adjacent face of the webbing, of a buckle comprising a base located wholly within the terminal loop and having a contracted neck that carries outstanding arms, said arms extending to the opposite side edges of the loop, a cross-bar that connects said arms and extends transversely across the outer face of one side of the loop and the band of webbing to be held, said cross-bar being arranged in a lower plane than the outstanding arms, and a locking-tongue pivoted upon the cross-bar and comprising a looped wire, the terminals of which constitute teeth that are located on opposite sides of the contracted neck and are arranged to force the portions of the band and loop beneath them into the space on opposite sides of the contracted neck and into engagement with the outstanding arms.

9. In a buckle of the class described, the combination with a base-frame having a contracted neck and outstanding arms, of a cross-bar secured in the outstanding arms and spaced from the contracted neck, and a tongue pivoted upon the cross-bar and having teeth which are located solely upon opposite sides of the neck, said teeth being of sufficient length to project into the space on opposite sides of the neck and beyond the plane of the adjacent face of said neck, whereby a band of webbing passed between the tongue and base will be pressed by the teeth into the spaces on opposite sides of the contracted neck and into engagement with said neck.

700,878. FIREPROOF SHUTTER. DOUGLAS, JR. JAMES G. WILSON, New York, N. Y. Filed Feb. 6, 1902. Serial No. 95,710. (No model.)

Claim.—1. As an improved article of manufacture, a fireproof shutter comprising an inner core or portion of wood and an exterior sheathing of metal having its outer face perforated, substantially as set forth.

2. As an improved article of manufacture, a shutter or door having a core of wood or the like and a sheathing of metal, the face of said metal having a plurality of perforations, substantially as set forth.

3. As an improved article of manufacture, a rolling or sliding shutter formed of wooden slats or bars and sheathings of metal around said slats or bars, said metal sheathings having in their outer faces perforations whereby communication is established between the outside air and the wooden core, substantially as set forth.

700,874. HEATING STOVE OR FURNACE. HENRY F. WILSON, Kansas City, Mo., assignor of one-half to HENRY SHANNON and BEN E. BOONER, Kansas City, Mo. Filed Jan. 21, 1897. Serial No. 643,376. (No model.)

Claim.—1. The combination, with a stove or furnace body, of a flue thereunder, a tube connecting one end of said flue to the lower front

portion of the body, a vertical flue connected to the opposite end of said flue, a chamber communicating with the upper back portion of the body and with said vertical flue, an opening in said chamber for a stovepipe, and a damper in said chamber, said damper being so movable as to cut off said chamber from the stove-body when in one position and to open communication therebetween when in a different position; substantially as described.

2. The combination, with a stove or furnace body, of a plurality of flues thereunder, a tube connecting the front ends of said flues to the lower front portion of the body, a plurality of vertical flues connected at their lower ends to the rear ends of said flues, a chamber communicating with the upper back portion of the body and with said vertical flues, an opening in said chamber for a stovepipe, and a damper in said chamber, said damper being so movable as to cut off said chamber from the stove-body when in one position, and to open communication therebetween when in another position, substantially as described.

3. The combination, with a stove or furnace body, of a plurality of flues thereunder, a tube connecting one end of said flues to the lower portion of said body, a plurality of vertical flues connected at their lower ends to the rear ends of said flues, a chamber communicating with the upper back portion of the body and with said vertical flues, an opening in said chamber for a stovepipe, and a damper in said chamber, said damper being so movable as to cut off said chamber from the stove-body when in one position, and to open communication therebetween when in another position, substantially as described.

700,875. CRANE. DAVID L. WATSON, Chicago, Ill., assignor to Theodore Watson Bros., Chicago, Ill. Filed Apr. 2, 1901. Serial No. 64,382. (No model.)

Claim.—1. In a crane the combination of the guide D and the lower E carrying the yoke F provided with the jaws b and c with the pulley A and the pulleys B and C provided with slots or notches substantially as described.

2. In a crane the combination of the guide D and the lower E provided with the jaws b and c and the steps ff with the pulley A and the pulleys B and C provided with slots or notches substantially as described.

700,876. CULTIVATOR. WILLIAM J. WENWALL, Kansas City, Mo., assignor of one-half to C. A. Frank, Kansas City, Mo. Filed Jan. 27, 1902. Serial No. 91,022. (2a added.)

Claim.—1. In a cultivator, a suitable frame, wheels supporting the same, a transverse shaft supported by said frame rearward of said wheels, beams and hanger-guards supported at their upper ends from said shaft and movable with the latter, said beams and hanger-guards extending at an angle to each other, cultivating appliances supported from said beams, a lever for operating said shaft and thereby synchronously raising said cultivating appliances and lowering said hanger-guards or lowering said cultivating appliances and raising said hanger-guards, and means for securing said lever in the desired adjustment.

2. In a cultivator, a pair of wheel-supported frames equipped with cultivating appliances and means for operating the latter, planks mounted to slide transversely of the machine in said frames, and a cast-plank pivotally connecting said sliding planks.

3. In a cultivator, a pair of wheel-supported frames equipped with cultivating appliances and means for operating the latter, planks mounted in said frames and free to move laterally but not forwardly or rearwardly thereof, parallel bars secured to said planks and engaging said wheel-supported frames, and a cast-plank pivotally connecting said sliding planks.

4. In a cultivator, a pair of wheel-supported frames, equipped with cultivating appliances and means for operating the latter, planks within said frames and adapted to slide laterally thereof, parallel bars secured to said planks and engaging the wheel-supported frames and provided with enlargements or heads for preventing the planks sliding forwardly or rearwardly in said wheel-supported frames, and a cast-plank pivotally connecting said sliding planks.

5. In a cultivator, a pair of wheel-supported frames equipped with cultivating appliances and means for operating the latter, said frames embodying front and rear transverse bars, planks adapted to slide laterally of said frames and provided with sets of parallel bars at opposite sides of their centers, said bars engaging the upper and lower edges of the transverse bars of the wheel-supported frames, and a cast-plank pivotally connecting said sliding planks.

6. In a cultivator, the combination of wheel-supported frames equipped with cultivating appliances and means for operating the latter, planks arranged to slide laterally of and supported by said frames, tongues hinged to the under side of said planks and projecting forwardly therefrom, and a cast-plank pivoted at its opposite ends upon said bolts above said sliding planks.

700,877. VALVE MECHANISM FOR HYDRAULIC ELEVATORS. HERMAN F. WITTE, Chicago, Ill., assignor to the Otis Elevator Company, East Orange, N. J., a Corporation of New Jersey. Filed Sept. 5, 1899. Serial No. 724,024. (2a added.)

Claim.—1. In a hydraulic-elevator hoisting mechanism, a hoisting-cylinder, a reversing-valve for controlling the supply to and exhaust from

said cylinder of an operating medium at high pressure, a discharge-tank for said hoisting-cylinder, a power-cylinder, a piston arranged therein and connected to said reversing-valve for actuating the latter, pipes delivering from said discharge-tank into both ends of said power-cylinder, whereby an operating medium at low pressure is delivered into either end of said power-cylinder to operate said piston in both directions, a pilot-valve for controlling said pipes, and means for returning the exhaust from said power-cylinder into said discharge-tank, as and for the purpose set forth.

2. In a hydraulic-elevator hoisting mechanism, a circulating system for a high-pressure operating medium, a main or reversing valve for controlling said system, a power-cylinder, a piston operating therein, a low-pressure hydraulic supply, pipes delivering from said supply into said power-cylinder, a pilot-valve arranged to control the admission of said low-pressure medium to either end of said power-cylinder at will, to operate said piston in either direction, and means whereby the discharge of said low-pressure operating medium is returned into the circulating system, as and for the purpose set forth.

3. In a hydraulic-elevator hoisting mechanism, a circulating system for a high-pressure operating medium, a main or reversing valve for controlling said system, a power-cylinder, a piston operating therein, a low-pressure hydraulic supply, pipes delivering from said supply into said power-cylinder, a pilot-valve arranged to control the admission of said low-pressure medium to either end of said power-cylinder, manually-operated means for moving said pilot-valve in either direction to open either end at will of said power-cylinder to the source of low-pressure supply to operate said piston in either direction, connections between said piston and said reversing-valve, and means actuated by the movement of said reversing-valve for moving said pilot-valve to close communication with the source of low-pressure supply of said cylinder and to open said cylinder to exhaust, as and for the purpose set forth.

4. In a valve mechanism for elevators, a main reversing-valve arranged to control the supply of high-pressure, operating medium to and from the hoisting-motor, in combination with a cylinder, a piston arranged therein and connected to said reversing-valve for operating the latter, a valve-chest, a low-pressure hydraulic supply, pipes delivering from said supply to said chest, an exhaust-pipe also communicating with said chest, ports arranged to open communication between said chest and each end of said cylinder, a pilot-valve for controlling said ports, manually-operated device for moving said valve to open said ports, and means operated by the movement of said piston for automatically moving said pilot-valve to close said ports and to open said cylinder-to-exhaust, as and for the purpose set forth.

5. In a valve mechanism for hydraulic elevators, a hoisting mechanism, a main or reversing valve arranged to control the supply of high-pressure, operating medium to and from the hoist-motor, a power-piston for operating said valve, a cylinder in which said piston operates, a source of low-pressure hydraulic supply for said power-cylinder, ports arranged

to deliver into each end of said power-cylinder and to each side of said piston, a pilot-valve for controlling said ports, manually-operated device for moving said pilot-valve in either direction to open either end of said power-cylinder to the source of low-pressure supply, and means actuated by the movement of said piston for moving said pilot-valve to close said cylinder to the source of low-pressure supply and to open the same to exhaust, as and for the purpose set forth.

6. In a valve mechanism for elevators, a main valve arranged to control the supply and discharge of a high-pressure operating medium to and from the hoisting-motor, in combination with a cylinder, a piston operating therein, connections between said piston and main valve for operating the latter, a pilot-valve, ports controlled by said pilot-valve, said ports leading to a different and independent source of supply from that of the hoisting-motor, means for manually moving said pilot-valve in either direction at will to open said cylinder to its independent source of supply, and means actuated by the movements of said piston when said pilot-valve is moved in either direction for automatically moving said pilot-valve in the opposite direction to close said cylinder to its source of supply and to open the same to exhaust, as and for the purpose set forth.

700,878. PHOTOGRAPHIC SHUTTER. ANDREW WILLIAMS, Rochester, N. Y. Filed Oct. 22, 1901. Serial No. 70,714. (Model.)

Claim.—1. A photographic shutter for making a series of graded exposures comprising, in combination with shutter-blades, mechanism for determining the duration of said various exposures, and motor mechanism for the shutter-blades, said mechanism being independent of each other, and a controlling-body common to both, substantially as shown and described.

2. A photographic shutter adapted to make a series of graded exposures ranging from brief duration to instantaneous, having mechanism comprising, in combination with shutter-blades, a retarding device for determining the duration of the various exposures, and motor mechanism for the shutter-blades independent of the retarding device, and a controlling-body common to both, substantially as set forth.

3. A photographic shutter for making both time and bulb exposures, having, in combination with shutter-blades, a master-arm with intermediate mechanism for moving the shutter-blades, a pair of detents for engaging said arm one for both exposures and the other for time exposures, and a release-lever for the exposure mechanism adapted to control both of said detents, substantially as set forth.

4. A photographic shutter for making exposures of different duration, having shutter-blades and mechanism for operating them, and a retarding mechanism acting independently of said shutter mechanism and a thumb-lever for setting said shutter mechanism, said thumb-lever being independent of the shutter mechanism, substantially as shown and described.

5. A photographic shutter for making exposures of different duration, having shutter-blades and mechanism for operating them, and retarding mechanism acting independently of the shutter mechanism and a spring-actuated thumb-lever for setting the shutter mechanism, said thumb-lever being adapted to return to its normal place while the mechanism is set and at rest without affecting said mechanism, substantially as shown and described.

6. A photographic shutter for making a series of exposures graded as to duration, having, in combination with shutter-blades and mechanism for operating them, a setting-lever, and retarding mechanism for determining the duration of the exposures, said retarding mechanism acting independently of the shutter mechanism and being adapted to set in motion the shutter mechanism independent of the setting-lever, substantially as set forth.

7. A photographic shutter for making a series of exposures graded as to duration, having, in combination with shutter-blades and mechanism for operating them, a retarding mechanism for the shutter mechanism acting independently of the shutter mechanism and adapted to be actuated by the shutter mechanism while moving to effect an exposure, substantially as described.

8. A photographic shutter for making a series of exposures graded as to duration, having, in combination with shutter-blades and mechanism for operating them, a retarding mechanism acting independently of the shutter mechanism and actuated by the shutter mechanism and a release-lever for the exposure mechanism, the latter making a part of its return motion independent of the retarding mechanism, substantially as described.

9. A photographic shutter for making a series of exposures graded as to duration, having, in combination with shutter-blades and mechanism for operating them, retarding mechanism for the exposure mechanism, actuated by the latter, and a release-lever for the exposure mechanism, there being an interval of time between the action of the release-lever upon the exposure mechanism and the action of the latter upon the retarding mechanism, substantially as set forth.

10. A photographic shutter for making a series of exposures graded as to duration, having, in combination with shutter-blades and mechanism for operating them, a retarding mechanism for determining the duration of the exposures, and means for controlling said exposure mechanism, the latter and the retarding mechanism acting independently of each other, substantially as set forth.

11. A photographic shutter adapted to make exposures of different duration, having shutter-blades and mechanism for operating them, a series of detents for the shutter mechanism, and a release-lever to successively engage the detents to control singly and release the shutter mechanism, substantially as set forth.

12. A photographic shutter adapted to make exposures of different duration, having shutter-blades and mechanism for operating them, a pair of detents for the shutter mechanism, and a release-lever controlling singly all of said detents and adapted for operating them moving in one direction to engage one detent and in the opposite direction to engage the other, substantially as shown and described.

13. A photographic shutter adapted to make exposures of different duration, having shutter-blades and mechanism for operating them, and a series of cam-follower detents for the shutter mechanism held to move in parallel planes, and a release-lever adapted to be actuated to neutralize the detents singly, substantially as and for the purpose specified.

14. A photographic shutter adapted to make exposures of different duration, having shutter-blades and mechanism for operating them, and a series of cam-follower detents for the shutter mechanism, and a release-lever adapted to be actuated by hand or by both pressure, said lever having a series of projections one to engage each of the detents, substantially as specified.

15. A photographic shutter adapted to make exposures of different duration, having shutter-blades and mechanism for operating them, a primary detent and two detents for the shutter mechanism, and a release-lever constructed to control singly all of said detents and adapted for actuating the several detents independently, with means for holding the two detents out of action, substantially as described.

16. A photographic shutter adapted to make exposures of different duration, having shutter-blades and motor mechanism therefor, a series of detents for the shutter mechanism, comprising two thin detents, and a release-lever to actuate the detents singly, with means for bringing the two detents successively into action, substantially as and for the purpose set forth.

17. A photographic shutter adapted to make exposures of different duration, having shutter-blades and motor mechanism therefor, including a pivoted arm, a series of cam-follower detents adapted to engage said arm at different points in its movement, and a release-lever constructed to control singly all of said detents and adapted for controlling the detents, substantially as stated.

18. A photographic shutter adapted to make time, bulb, and graded exposures, comprising shutter-blades and mechanism for operating them, and retarding mechanism for the shutter mechanism, and companion detents for the shutter mechanism to effect time and bulb exposures respectively, and a controlling-body common to both detents and the retarding mechanism, substantially as shown and described.

19. A photographic shutter adapted to make time, bulb, and graded exposures, comprising shutter-blades and mechanism for operating them, and retarding mechanism for the shutter mechanism, and companion detents for the shutter mechanism to effect time and bulb exposures respectively, and a controlling-body common to both detents and the retarding mechanism, said controlling-body being adapted to hold both detents in motion or to allow them to move into action successively, and to hold the retarding mechanism out of action, substantially as and for the purpose specified.

20. A photographic shutter adapted to make time, bulb, and graded exposures, comprising shutter-blades and mechanism for operating them, and retarding mechanism for the shutter mechanism, and companion detents for the shutter mechanism to effect time and bulb exposures respectively, and a controlling-body common to both detents and the retarding

mechanism said controlling-body being adapted to be moved to simultaneously hold said detents and the retarding device out of action, substantially as specified.

21. A photographic shutter adapted to make time, bulb, and graded exposures, comprising shutter-blades and mechanism for operating them, and retarding mechanism for the shutter mechanism, and composition detents for the shutter mechanism to effect time and bulb exposures respectively, and a controlling-body common to both detents and the retarding mechanism, said controlling-body being adapted to hold the retarding mechanism out of action while the detents act, substantially as set forth.

22. A photographic shutter adapted to make time, bulb, and graded exposures, comprising shutter-blades and mechanism for operating them, and retarding mechanism including an eccentric arm, for the shutter mechanism, and a controlling-body common to both said mechanisms engaging the eccentric arm, there being detents for the shutter mechanism engaged by said controlling-body, the latter having in part the form of an eccentric and in part the form of a mutilated disk, substantially as shown and described.

23. A photographic shutter adapted to make graded exposures, having shutter-blades and mechanism for operating them, and a retarding device for controlling the exposure mechanism, and a spring for returning the retarding device to its normal place, substantially as shown and described.

24. A photographic shutter adapted to make graded exposures, having shutter-blades and mechanism for operating them, and a retarding device for the shutter mechanism comprising an arm pivoted at one end, an air-pump, and a lever carried by said arm to operate the pump, and means for turning the arm to prearranged positions, and to operate said lever, substantially as and for the purpose set forth.

25. A photographic shutter adapted to make graded exposures, having shutter-blades and mechanism for operating them, and a retarding device for the shutter mechanism comprising a pivotal arm, an air-pump, and a lever carried by said arm movably connected with the air-pump, with means to move the lever independent of the carrying-arm, substantially as set forth.

26. A photographic shutter adapted to make graded exposures, having shutter mechanism, and retarding mechanism for controlling the shutter mechanism, comprising a pump-barrel with plunger therein, a pivoted arm and means to control it, a lever held pivotally by said arm and connected with said plunger, and means independent of the pivoted arm to move the lever through distances varying according to the position of the pivoted arm, substantially as and for the purpose specified.

27. A photographic shutter adapted to make graded exposures, having shutter mechanism, and retarding mechanism comprising a pivoted arm for controlling the shutter mechanism, and means including a graduated scale and indicator therefor, for controlling the pivoted arm, substantially as set forth.

700,879. GAME APPARATUS. HENRY WOOLFE, Gloucester, England. Filed June 7, 1901. Serial No. 68,088. (No model.)

Claim.—1. A game apparatus for practicing shooting comprising a pistol, a target arranged opposite thereto, a tray arranged in front of the target to receive projectiles which fall from the target, falling to pass through the bull's-eye, means behind the target for collecting projectiles passing through the bull's-eye and returning them to the operator, and means operated by the person removing the projectile for permitting the projectile which has passed through the bull's-eye to pass out upon the said tray, substantially as described.

2. A toy shooting apparatus comprising a pistol pivoted to a casing, a target in front of the pistol provided with a hole or slot, a hinged tray arranged to receive projectiles which fall to pass through said slot, a chute beneath the hinged tray communicating with a receptacle outside the cas-

ing, and receptacle within the casing for receiving projectiles which have passed off the tray laterally, substantially as described.

3. A toy shooting apparatus comprising a pistol, a target opposite thereto, a hinged tray adjacent to the target, a counterweighted arm connected to said tray, a box at the back of the target, a spring-plate having a projection fitting into a cut-away portion of the box, the free end of said arm engaging a hole in said box, a bar closing the passage from the box to the tray, and means for raising the bar so as to free the said passage, substantially as described.

4. A toy shooting apparatus comprising a projectile-ejecting means, a target arranged opposite thereto, a tray hinged in front of the target, a receptacle at the back of the target, a hinged spring-plate projecting inside the said receptacle and locking the said hinged tray, a minute-controlling arm blocking a minute-aperture in the target, a ball-crank lever, and an arm for operating the same, substantially as described.

5. A toy shooting apparatus comprising a pistol, a target opposite thereto having a slot formed therein, a tray provided with an arm for controlling the same, chains leading from the target, a receptacle at the rear of the target, a spring-plate arranged in said receptacle, an arm for blocking the said slot, a ball-crank lever, and an arm for operating the same, a receptacle for return projectiles, and a receptacle for retaining other projectiles within the apparatus, substantially as described.

6. A toy shooting apparatus or game mechanism, comprising a casing including a target, means for discharging missiles at the target, the center of the said target being provided with an aperture through which successful shots may pass, means operated by the weight of the missile for permitting the successful shots to pass to the outside of the said casing so as to return them to the party shooting, and means for preventing the return of unsuccessful shots to the operator, substantially as described.

7. A game apparatus comprising an enclosing casing, an apertured target mounted therein, a pivoted shooting mechanism mounted in the wall of the casing and capable of being aimed at the target, means opposite the aperture of the target for collecting the missiles of successful shots and returning them to the player, means for catching unsuccessful shots and depositing some of them permanently within the apparatus while others are left in such a position that a successful shot may cause them to be delivered outside the apparatus, substantially as described.

700,880. STEAM-SEPARATOR. WARREN W. WRAY, Lowell, Mass. Filed Jan. 12, 1905. Serial No. 68,461. (No model.)

Claim.—1. A steam-separator constructed with a case open at its extremities, forming an interior chamber, a perforated baffling-cylinder extending through said chamber, and a baffling-cone having its points projecting in opposite directions longitudinally of the cylinder forming a deflecting-diaphragm within the cylinder intermediate of the ends thereof, said case formed with a discharge-orifice.

2. A steam-separator constructed with a case open at its extremities forming an interior chamber, a perforated baffling-cylinder extending through said chamber into which steam may enter at either end, and a double-pointed baffling-cone located within the cylinder intermediate of the ends thereof the points of the cone extending toward both ends of the cylinder longitudinally thereof said case provided with a discharge-orifice.

3. A steam-separator constructed with a case open at its extremities forming an interior chamber, a perforated baffling-cylinder within the chamber, and formed integral with said case into which steam may enter in either direction, and a double-pointed baffling-cone within said cylinder constructed to deflect steam entering into either end of the cylinder, the points of the cone extending toward both ends of the cylinder longitudinally thereof, said case formed with a discharge-orifice.

4. A steam-separator constructed with a case open at its extremities forming an interior chamber, a perforated baffling-cylinder within said chamber and formed integral with said case into which steam may enter in either direction, and a hollow conical device having cone-shaped points extending toward the two ends of the cylinder to deflect steam entering

the cylinder in either direction, said cone-shaped points formed with openings at the extremities thereof, and deflecting devices engaged in said openings, said cone formed with a discharge-orifice.

700,881. STIRRUP. ISAAC YERGEN, Chester, N. H. Filed Aug. 21, 1901. Serial No. 73,081. (No model.)

Claim.—1. In a stirrup, the combination of a stirrup frame or body, and a hinged upright frame arranged at the back of the stirrup frame or body and conforming to the general configuration of the same and pivotally connected with the said stirrup frame or body at the bottom thereof, whereby it is adapted to swing downward and rearward to release the feet of a rider, substantially as described.

2. In a stirrup, the combination of a stirrup frame or body, an upright frame arranged at the back of the stirrup frame or body and consisting of an anterior lower portion hinged to the bottom of the stirrup frame or body at the lower free thereof, and an upper portion arranged substantially within the stirrup frame or body, said upright frame covering the stirrup frame or body and engaging the same, substantially as described.

3. In a stirrup, the combination of a stirrup frame or body, an upright frame arranged at the back thereof and hinged to the bottom of the same, and the transverse top piece extending across the upright frame and having a curved lower edge, substantially as described.

4. In a stirrup, the combination of a stirrup frame or body, an upright frame hinged to the bottom of the stirrup frame or body and provided with a flattened upper portion, the transverse top piece secured to the flattened portion of the upright frame, and a spring for holding the upright frame normally in such position, substantially as described.

700,882. FASTENER FOR JAR-COVERS. JAMES P. YOUNG, Monmouth, N. J. Filed June 7, 1901. Serial No. 68,000. (No model.)

Claim.—1. In a jar-closure, a ball secured to the jar, a cover, a hemispherical elevation thereon having a groove in which said ball is adapted to seat, a slotted lever mounted on said ball, and a groove in said cover in which said lever works to seat and unseat the ball, substantially as shown and described.

2. In a jar-closure, recesses in the sides of the jar, a ball pivoted therein, a cover having a grooved apex to receive said ball, a slotted lever mounted on said ball, and the cover provided with a bearing-orifice to assist said lever in seating and unseating the ball, substantially as shown and described.

3. In a jar-closure, a ball pivoted in the sides of the jar, a cover having a hemispherical elevation thereon, a groove in said elevation having the center of its base raised and rounding toward the ends of the groove, a slotted lever mounted on said ball and adapted to seat in said groove having a raised base, and a groove at the apex of said hemispherical elevation at right angles to said first-mentioned groove in which said ball is adapted to seat, substantially as shown and described.

4. In a jar-closure, a ball pivoted in the sides of the jar, a cover hav-

ing a hemispherical elevation thereon, a groove in said elevation having its base slanting upwardly to the center, a slotted lever to seat in said groove, having a transverse bar at one end, mounted on said ball, and a groove at the apex of said hemispherical elevation at right angles to said first-mentioned groove in which said ball is adapted to seat, substantially as shown and described.

5. A jar-closure consisting of a cover having a hemispherical elevation thereon, a groove in said elevation having its base slanting upwardly from each end to the center, a slotted lever mounted on said ball, a groove at the apex of said hemispherical elevation at right angles to said first-mentioned groove, and a ball to seat in said groove at the apex of said hemispherical elevation, in combination with a jar having recesses for the reception of the ends of said ball, substantially as shown and described.

6. In combination with a jar having its top edge slanting inwardly, a cover to seat on said slanting edge having an annular depending flange to fit inside the mouth of the jar, a hemispherical elevation on said cover having a grooved apex, a ball pivotally secured in the sides of said jar adapted to seat in said groove, a slotted lever mounted on said ball, and a groove in said cover in which said lever works to seat and unseat said ball, substantially as shown and described.

700,888. SUSPENDER. ALFRED H. ZIMMER, Boston, Mass. Filed Aug. 18, 1901. Serial No. 73,387. (No model.)

Claim.—1. In a suspender, a loop end or fastening-piece for buttoning the suspender in position, having at its upper end or middle part a holding-piece of thin, strong fabric immovably secured thereto, a web end of the suspender adjacent thereto, a non-metallic connection passed about said middle part of said loop end and including said fastening-strip and secured thereto by lines of stitches or equivalent means.

2. In a suspender, a loop end or fastening-piece for buttoning the suspender in position, having at its upper end or middle part a holding-piece of thin, strong fabric, an unyielding clamping-clip for holding the two in immovable relation, a web end of the suspender adjacent thereto, a non-metallic connection passed about said middle part of said loop end and including said fastening-strip and secured thereto by lines of stitches or equivalent means.

3. In a suspender, a loop end or fastening-piece for buttoning the suspender in position, having at its upper end or middle part a holding-piece of thin, strong fabric immovably secured thereto, a web end of the suspender adjacent thereto, a non-metallic connection passed about said middle part of said loop end and including said fastening-strip and secured thereto by lines of stitches or equivalent means, and means for preventing said loop end and said connection from moving laterally on each other.

4. The combination with the web of a suspender, a loop end or fastening-piece for buttoning purposes, and a connecting-piece secured to the suspender-web and passing about the middle of the loop end, of the herein-described means for transferring the strain from the loop end to the suspender-web and retaining the said loop end in position and preventing lateral movement thereof relatively to said connecting-piece, said means consisting of a piece of thin, strong material immovably fastened to the middle part of the loop end and connecting-piece and extending upwardly therefrom, said upwardly-extending end being permanently secured between the adjacent sides of the connecting-piece.

700,884. PYROXYLIN COMPOUND. RUDOLF STAHL, Berlin, Germany. Filed Nov. 17, 1900. Serial No. 34,000. (No specimens.)

Claim.—A new pyroxylin or nitrocellulose composition containing pyroxylin or nitrocellulose with a compound ester of carbonic acid and monosubstituted hydrocarbon of the aromatic series (of the group including diphenylcarbonate, triphenylcarbonate, and triphenylmethylcarbonate.)

700,885. PYROXYLIN COMPOUND. RUDOLF STAHL, Berlin, Germany. Filed July 2, 1901. Serial No. 68,913. (No specimens.)

Claim.—1. The process of manufacturing pyroxylin compounds which consists in combining nitrated cellulose with one or more members

of the compound esters of phosphoric acid and monoxygenated hydrocarbons of the aromatic series (consisting essentially of triphenylphosphate, triisopropylphosphate and trimethylphosphate,) as described.

2. The process of manufacturing pyroxylin compounds which consists in combining nitrocellulose with one or more members of the compound esters of phosphoric acid and monoxygenated hydrocarbons of the aromatic series (consisting essentially of triphenylphosphate, triisopropylphosphate and trimethylphosphate,) and working the resulting mixture up into the material, as specified.

3. The process of manufacturing pyroxylin compounds which consists in combining nitrocellulose with one or more members of the compound esters of phosphoric acid and monoxygenated hydrocarbons of the aromatic series (consisting essentially of triphenylphosphate, triisopropylphosphate and trimethylphosphate,) and an auxiliary solvent, as specified.

4. As a new article of manufacture a solid composition to be used as a material in the arts and trades and composed essentially of nitrocellulose, and one or more members of the compound esters of phosphoric acid and monoxygenated hydrocarbons of the aromatic series (consisting essentially of triphenylphosphate, triisopropylphosphate and trimethylphosphate,) as specified.

5. As a new article of manufacture, a solid composition to be used as a material in the arts and trades and composed essentially of nitrocellulose, and one or more members of the compound esters of phosphoric acid and monoxygenated hydrocarbons of the aromatic series (consisting essentially of triphenylphosphate, triisopropylphosphate and trimethylphosphate,) substantially as described and in the proportions specified.

6. As a new article of manufacture, a solid composition to be used as a material in the arts and trades and composed essentially of nitrocellulose, and one or more members of the compound esters of phosphoric acid and monoxygenated hydrocarbons of the aromatic series (consisting essentially of triphenylphosphate, triisopropylphosphate and trimethylphosphate,) and an auxiliary solvent, as specified.

700,886. APPARATUS FOR HANDLING GRAIN. ARTHUR A. KIRBY, Winnipeg, Canada. Filed Feb. 4, 1901. Serial No. 46,966. (No model.)

Claim.—1. In a portable elevator for grain and the like, the combination with the truck, and supporting-frame, of a tube, enclosing bands in which said tube is adjustably held, bolts for tightening said enclosing bands, a curved plate covered to said enclosing bands, and having a projection on its under side in which is a circular hole, a shaft or spindle passing through said hole, bearings in which said shaft is journaled, a bearing-frame supporting said bearings, a block on which said bearing-frame is firmly secured, a platform to which said block and bearings are pivotally attached, and, means for raising grain and the like in said tube, as and for the purpose specified.

2. In a portable elevator for grain and the like, the combination with the truck and supporting-frame, of a tube having a suitable flexible casing about it, the bearings in which each tube is suitably supported, a bearing-frame supporting said bearings, a block on which each bearing-frame is firmly secured, a platform, a belt passing loosely through said platform

and covered into said block or bearing-frame, and means for raising grain and the like in said tube, as and for the purpose specified.

3. In a device of the class described, the combination with the cylindrical elevating-tube, the longitudinal partition located therein and the pair of sprocket-chains and their upper and lower sprockets, of flat and substantially semicircular conveying buckets or scoops attached to said chains at intervals, substantially as described.

700,887. GAME DEVICE. GEORGE F. BARNES, Patuxent, N. Y., assignor of one-fourth to Frank Railway, Patuxent, N. Y. Filed Jan. 26, 1901. Serial No. 60,292. (No model.)

Claim.—1. A game device comprising a hollow rectangular body or inclosing case with plain floor or bottom, having a rectangular aperture substantially central within the body, with a space around all sides thereof, said aperture being open at one end and closed at the other with the closed end nearer the end of the case than its open end and spheres, as marbles, in the body adapted to roll around and within said inner aperture, the spheres or marbles being of different colors, and a table of said color with the body, substantially as shown and described.

2. A rectangular case having substantially central longitudinal aperture open at one end, a plurality of spheres in said aperture and a cover for said case having open its under side a depending block disposed at its longitudinal center and adapted when the cover is in place to coincide with and close the open end of said aperture, substantially as shown and described.

3. A game device comprising a hollow rectangular body longer than wide, a rectangular aperture longer than wide formed longitudinally within the body with its side imperforate and parallel with the sides of the body, said aperture being closed at one end and open at the other with its end wall imperforate, there being space all around the inner aperture, the walls of the latter and of the body being equal in height, and a series of spheres adapted to roll upon the floor of the body, substantially as described.

700,888. FLUID FOR PROMOTING COMBUSTION. TIMOTHY BATTENIN, Genoa, Italy. Filed Dec. 26, 1901. Serial No. 71,964. (No specimens.)

Claim.—A fluid for promoting combustion which comprises a solution consisting of one part by weight of nitrate of sodium and two parts by weight of carbonate of sodium, substantially as specified.

700,889. RETRACTING AND REFINING ASPHALTUM. ALVIN F. L. BELL, Carpinteria, Cal., assignor to The Alcatraz Company, San Francisco, Cal., a Corporation of West Virginia. Filed May 18, 1901. Serial No. 64,403. (No model.)

Claim.—1. In asphaltum extracting and refining apparatus, a vertical series of crushing-rollers arranged in pairs, laterally-adjustable bearings for said rollers, horizontal channel-beams 11 above and below said bearings supporting the same, struts 14 between the bearings, adjustable through-bolts 15 passing through the webs of the channel-beams outside the bearings, and transverse chimes or packing 16 for adjusting the horizontal distance between said rollers, substantially as specified.

2. In asphaltum extracting and refining apparatus, a pair of col-

lating rollers, each provided with spaced rows of removable spaced teeth borne in channelled sections 21 in said rollers, and through-rolls 22 engaging grooves in said teeth and said sections, for holding the teeth in position, the teeth of one roller being located opposite the spaces of the other roller, whereby the said teeth intermesh, substantially as specified.

3. In asphaltum extracting and refining apparatus, a pair of col-lating rollers, horizontal channel-beams 11 for supporting the bearings of said rollers above and below, sliding bearings borne on said channel-beams, through-bolts 15 passing through the webs of the channel-beams outside the bearings, struts 14 between the bearings, transverse chimes 16, and followers 17, overlapping the bolts 15, said bolts and followers provided with holes for the insertion of pins to prevent the bolts from working out, substantially as specified.

4. In asphaltum extracting and refining apparatus, a series of crushing and disintegrating rollers arranged in pairs, one above the other, the rolls of each successive pair from above downward being nearer together than those of the preceding pair, said rollers being mounted in movable and adjustable bearings that slide between horizontal beams forming a part of the main frame and projecting laterally beyond the same on each side, whereby the said rollers may be moved out laterally, clear of the main frame while supported thereon, substantially as specified.

5. In asphaltum extracting and refining apparatus, a pair of col-lating rollers, removable spaced teeth suitably arranged in each roller, with annular interspaces, said teeth of one roller being located opposite the spaces of the other roller to intermesh, means for adjusting the distance between said rollers, and adjustable stationary carriages located between each ring of teeth in the interspaces, to keep said interspaces clear, substantially as specified.

700,890. CAN-TESTING MACHINES. HENRY C. BLAKE, Oakland, Cal. Filed June 14, 1901. Serial No. 64,507. (No model.)

Claim.—1. In a machine of the character described, a pair of colliding-troughs arranged side by side, a pair of supporting members for each trough, and means for adjusting either pair of said supporting members independently of the other pair to adjust one of the troughs independently of the other, substantially as described.

2. In a machine of the character described, a pair of colliding-troughs arranged side by side, a pair of supporting-plates for the ends of each trough, the adjacent plates at the respective ends of the trough being arranged to slide thereon upon the other, and means for adjusting each of said plates independently of the other plates, substantially as described.

3. A tubular open-ended colliding-trough having a single narrow longitudinally-arranged slot terminating at points intermediate of the ends of the trough, and a closure 17 for the open end of the trough, substantially as described.

4. A tubular colliding-trough having a single narrow longitudinally-arranged slot terminating at points intermediate of the ends of the trough, a fill-opening at one end of the trough, an auxiliary fill-opening in the body of the trough, and a feed-pipe 11 leading into said auxiliary fill-opening, substantially as described.

5. In a can-and-colliding machine, a heater comprising a hollow trough upon which the cans to be operated upon are adapted to run and having sides inclined outwardly and upwardly, a plurality of burners disposed longitudinally of said trough and beneath the lower central portion thereof, said trough being of a width less than the length of the cans to permit the heating of both ends of said cans simultaneously, and a heat non-conducting filling in the trough and arranged to underlie the central portion of the cans, substantially as described.

6. In a can-and-colliding machine, a heater comprising a disengaged support for the cans to be operated upon and provided with upwardly and outwardly inclined sides and a flat upper surface upon which the cans are

adapted to run, and a plurality of burners disposed longitudinally of said trough and beneath the lower central portion thereof, said trough being of a width less than the length of the cans to permit the heating of both ends of said cans simultaneously, substantially as described.

7. In combination, a slotted tubular heater, and a correspondingly-slotted colliding-trough seated in said heater and provided with lateral projections along its upper portion and engaging the edges of the tube surrounding the slot in the latter, substantially as described.

8. In combination, a slotted tubular heater, a correspondingly-slotted colliding-trough, and means for supporting the colliding-trough in the heater comprising longitudinally-disposed shoulders 17 at the upper portion of the sides of the former bearing upon edges 18 of the latter, substantially as described.

9. In combination, a slotted tubular heater, a correspondingly-slotted colliding-trough seated in said heater and provided with lateral projections engaging the edges of the heater surrounding the slot in the latter, and a series of burners arranged longitudinally of the tubular heater beneath the same and projecting slightly therethrough through suitable apertures formed in the bottom thereof, substantially as described.

700,891. CAN-TESTING APPARATUS. HENRY C. BLAKE, Oakland, Cal. Filed Nov. 22, 1901. Serial No. 65,060. (No model.)

Claim.—1. In a can-testing apparatus, the combination with a rotatable wheel, of anchor-disks attached to and carried by the rotatable wheel, means for placing the open end of the can to be tested in contact with said anchor-disk so as to cause the can to adhere thereto, and device whereby an outward pressure is exerted upon the can held by the disk.

2. A can-tester comprising an anchor-disk and means for placing the open end of a can to be tested in contact with said anchor-disk, whereby the disk is compressed by each movement so that when the pressure is released the disk will expand and cause a vacuum within the can, and device for exerting an outward pressure to the held can.

3. In a can-tester, the combination with the anchor-disk, of a spring-pressed valve arranged therein, said valve designed to bear against the open end of the can to be tested and to exert an outward pressure thereon.

4. The combination with the anchor-disk, of a spring-pressed valve arranged therein so as to bear against and to exert an outward pressure to the can being tested, and means for placing the open end of the can to be tested in contact with the anchor-disk.

5. The combination with a rotatable wheel, means for imparting rotation thereto, the can-holding rings arranged to cap ends of the rotatable wheel and moving in unison therewith, can-held disks by which cans are delivered to said holding-rings, device whereby the cans are held in place,

a series of anchor-disks attached to the rotatable wheel, device by means of which the can is forced against its anchor-disk, device for exerting an outward pressure to the cans being tested, and means for releasing the perfect or non-leaky cans.

6. The combination with rotatable mechanism, a series of anchor-disks carried thereby, means whereby the open end of the can to be tested is placed in contact with the anchor-disk, spring-held valve for exerting an outward pressure upon the held can, and device whereby the perfect or non-leaky cans are removed from the anchor-disks.

7. In a can-tester, the combination with rotatable mechanism, a series of anchor-disks attached thereto which receive and hold the cans, means for exerting a constant out pressure upon the held cans, a bath through which the cans are conveyed so as to wash same, and means whereby the tested cans are removed from the anchor-disks.

8. The combination with a can-tester, of a series of compressible anchor-disks attached thereto, and means whereby an outward pressure is exerted upon the can held by the disk.

700,893. TAP FOR CUTTING SCREW-THREADS. CHARLES E. BLACKBURN and GEORGE J. FORTIN, Wolverhampton, England. Filed Jan. 2, 1900. Serial No. 88,574. (No model.)

Claim.—The herein-described tap provided with threaded portions separated by flanges, each threaded portion having a cutting edge and a heel, the threads being "bashed off" toward the heel and said heel parts being of substantially the same diameter as the cutting-edge parts, as and for the purpose set forth.

700,898. GAS-CHUCK FOR BURNER OR SIMILAR BURNERS. FRANK M. BROWN, Brooklyn, N. Y. Filed Dec. 11, 1901. Serial No. 88,487. (No model.)

Claim.—1. In a Bunsen burner the combination of a burner-tube provided with air-holes, a hollow check adapted to close the end below the air-holes and having an upwardly-extending threaded and hollow stem provided with a needle-valve, a gas-regulating cap embodying a seat for the needle-valve threaded to the stem and a flange on the cap, the flange

being accessible from the exterior through the air-holes in the tube, where by the supply of gas may be regulated without affecting the supply of air.

2. In a Bunsen burner the combination of a burner-tube provided with air-holes, a hollow check adapted to close the end of the tube below the air-holes, passage-ways for the gas through the check, a needle-valve extending upwardly from the check, a gas-regulating cap threaded to the check embodying a seat for the needle-valve, said cap being located opposite the air-holes in the tube whereby it may be actuated through them, and the supply of gas regulated without affecting the supply of air.

3. In a Bunsen burner the combination of a burner-tube provided with air-holes, a hollow check adapted to close the end of the tube below the air-holes and provided with threads for attachment to a gas-fitter, an upwardly-extending threaded stem provided with passage-ways for the gas and a needle-valve, a perforated gas-regulating cap threaded to the stem and adapted to inclose the gas-passages in it and provided with a seat for the needle-valve through which the gas escapes into the burner-tube, the parts being so proportioned and arranged that when assembled the cap is accessible and may be manipulated through the air-holes in the tube for cutting off the supply of gas without affecting the supply of air.

700,894. PEDISTAL. FERRY BROWN, Wilmington, Del. Filed Feb. 26, 1901. Serial No. 88,598. (No model.)

Claim.—1. In a device of the character described, a pedestal, a journal-box, and a wearing-plate interposed between the pedestal and box and having horizontal flanges to hold the same in position and vertical flanges to take the wear off the flanges of the said journal-box, substantially as described.

2. In a device of the character described, a journal-box, a pedestal-standard comprising two sides connected by a web, and an anti-friction-roller supported between said web and said journal-box, substantially as described.

3. In a device of the character described, a pedestal-standard comprising two sides connected by a web having a pocket formed therein, and an anti-friction-roller supported in said pocket, substantially as described.

4. In a device of the character described, a journal-box having flanges, a pedestal-standard comprising two flanged sides connected by a web, an anti-friction-roller supported between said web and said box, and a wearing-plate interposed between the flanges of said box and the flanges of said pedestal sides, substantially as described.

5. In a device of the character described, a pedestal and journal-box, an anti-friction-roller supported by the pedestal and a wearing-plate attached to the box, the said wearing-plate having horizontal flanges thereon to hold the same in position and vertical flanges to take the wear off of the flanges of said box.

6. In a device of the character described, a pedestal-standard having an integral loop for the attachment of the tie or brace rod.

7. In a device of the character described, pedestal having standards and integral loops on the ends of said standards, and a tie or brace rod secured in said loops.

8. A pedestal having integral pockets for anti-friction-rollers and loops for the attachment of the tie or brace rod.

700,895. JOINT-CLOSER FOR RUBBER-TIRE-GETTING MACHINES. JESSE A. BROWN, Akron, Ohio, assignor to the Goodyear Tire and Rubber Company, Akron, Ohio. Filed July 31, 1901. Serial No. 78,482. (No model.)

Claim.—1. In a machine for bringing together the ends of vul-

rubber tire, the combination with a pivot to support a wheel-hub, of a lever pivoted at one end on said pivot bearing a sliding block, having rollers to press the sides of said tire, means for causing said rollers to approach and recede from each other, and bars secured to said block, substantially radial to said wheel having sliding stops thereon with blades to pass under said tire, substantially as shown and described.

2. The combination in a machine for bringing together the ends of solid-rubber vehicle-tires, of a frame, a journal for the wheel secured thereto, a lever pivoted at one end on said pivot bearing a sliding block, having rollers to press the sides of said tire in the wheel-channel and compressing it laterally to force its fulcrum forward, substantially as shown and described.

3. In a machine for bringing together the ends of solid vehicle-tires, the combination with a supporting post or frame bearing near its top an anchor-pin, and below it a pivot for the wheel, of a lever pivoted on said wheel-pivot and bearing a longitudinally-movable block bearing rollers to compress the sides of the tire, and blades to slide under and raise said tire in advance of said rollers, in combination with a second lever pivoted to said first lever near its free end and also pivoted to the free end of a bar, attached at its opposite end to said anchor-pin, substantially as shown and described.

4. In a machine for bringing together the ends of solid-rubber vehicle-tires, the combination with a supporting post or frame bearing a pivot for the wheel with means for centering the wheel thereon, of a lever pivoted on said wheel-pivot bearing a longitudinally-movable block having rollers to compress the sides of the tire and blades to slide under and raise said tire in advance of said rollers, and a second lever pivoted to said first lever, mounted on a movable fulcrum connected with said frame and adjustable with reference thereto, substantially as shown and described.

5. In a machine for bringing together the ends of solid-rubber vehicle-tires, the combination with a supporting post or frame, having a pivot for the wheel-hub, and an anchor-pin, of a lever pivoted on the wheel-pivot, and bearing a longitudinally-adjustable slide having means for raising, compressing and forcing forward the fulcrum of the tire, of an auxiliary lever pivoted to the free end of said first lever and pivoted on a pin in a bar adjustably connected with said anchor-pin, substantially as shown and described.

6. An improved machine for bringing together the ends of solid-rubber vehicle-tires consisting of a supporting post or frame bearing an off-center bar with a pivot for the wheel, and an anchor-pin; a lever pivoted on said wheel-pivot, with a sliding block thereon having rocking-bars having reversible rollers to compress the sides of the tire, and means for rocking said bars to cause said rollers to approach or recede from each other, and parallel bars adapted to approach and recede from each other having slides bearing blades to pass under and raise said tire; a bar having notches to engage said anchor-pin, and a lever pivoted on the free end of said bar and pivoted near the free end of said first lever, substantially as shown and described.

700,896. CASH-REGISTER. THOMAS GANNETT, Dayton, Ohio, assignor, by means of attorneys, to the National Cash Register Company, Jersey City, N. J., a Corporation of New Jersey. Filed Mar. 14, 1895. Serial No. 65,705. (No model.)

Claim.—1. In a cash-register the combination with a series of operating-levers, of rotary indicators, devices for operating the indicators to turn the same forward past the point at which they are to be arrested

upon their return, means for returning the indicators and graduated means operated by the levers for arresting and holding the indicators at the proper points in their return movements while the levers return to normal position.

2. In a cash-register the combination with a series of operating-levers, of rotary indicators, devices for operating the indicators to turn the same forward past the point at which they are to be arrested upon their return, means for returning the indicators and means arranged to be actuated by the levers for arresting the indicators upon their return movements independently of the movements of the levers.

3. In a cash-register, the combination with a series of operating-levers, of a series of rotary indicators arranged to be moved forward upon one stroke of the levers and back again upon the reverse stroke, and graduated arresting devices actuated by the forward stroke of the levers to arrest the indicators at the proper points in their return movements.

4. In a cash-register, the combination with a series of operating-levers, of a series of rotary indicators arranged to be moved forward upon one stroke of the levers and back again upon the reverse stroke, and graduated means actuated by the levers for arresting and holding the indicators at the proper points in their return movements while the levers return to normal position.

5. The combination of the key-levers A having the fingers G provided with the laterally-projecting studs J arranged in graduated order, the pivoted frame I having the longitudinal and transverse slots b c co-operating in the manner described with the studs J, the rack K moving with the frame I, the movable registering-frame carrying a registering-wheel having a pinion adapted to cooperate with the rack K, and means for moving said frame to and from position for the rack and pinion to co-operate with each other.

6. The combination, with the special key-levers, of the shaft D' and the sleeves located thereon, the depending arm G' co-operating with the studs H' upon the key-levers, the special registers C', and means intermediate said shaft and sleeves and special registers for causing the operation of the special key-levers to estimate such special registers, substantially as described.

7. The combination of a plurality of operating-levers, an oscillatory indicator-wheel, a spring operating to yieldingly hold said wheel in and return it to initial position, means intermediate said wheel and the operating-levers for causing the operation of any one of the levers to turn the wheel from initial position, and a plurality of stops co-operating with the levers and adapted to be projected by them into the path of the indicator after the latter has been moved from initial position past the stop to be operated so as to arrest said indicator upon its return.

8. The combination of a plurality of operating-levers, an oscillatory indicator-wheel, a spring operating to yieldingly hold said wheel in and return it to initial position, means intermediate said wheel and the operating-levers for causing the operation of any one of the levers to turn the wheel from initial position, a plurality of stops co-operating with the levers and adapted to be projected by them into the return-path of the indicator after the latter has been moved from initial position, means for holding the projected stop in such position after the release of the corresponding operating-lever, and means for releasing said stop upon the operation of another key and projection of another stop.

9. The combination of a plurality of operating-levers, an oscillatory indicator-wheel, a spring operating to yieldingly hold said wheel in and

return it to initial position, means intermediate end wheel and the operating-levers for causing the operation of any one of the levers to turn the wheel from initial position, a plurality of reciprocating stop-rods carrying steps adapted to be projected into the return-path of the indicator after the same has been moved from initial position, a movable supporting-bar cooperating with projections upon each stop-rod to hold the projected steps in position, and means intermediate said bar and the operating-levers for moving said bar to release the projected steps.

10. The combination of a plurality of operating key-levers, an indicator-wheel, a spring for yieldingly holding said wheel in and returning it to initial position, means intermediate said wheel and the key-levers for causing the operation of any one of the latter to move the wheel from initial position, a plurality of vertically-sliding stop-rods adapted to be lifted by the operation of the respective key-levers and each carrying a step adapted when the rod is lifted by its corresponding key-lever to project into the return-path of the indicator-wheel which has been moved from initial position by the operation of the key-lever, a movable supporting-bar cooperating with the stop-rods to hold the operated rods in elevated position, and means intermediate said bar and the key-levers for moving said bar to release the elevated rods.

11. The combination of a plurality of operating key-levers furnished on a horizontal axis, an indicator-wheel turning upon a vertical axis, a spring operating to yieldingly hold the indicator-wheel in and return it to initial position, means intermediate the wheel and key-levers for causing the operation of any one of the latter to turn the wheel from initial position, and a plurality of steps adapted to be projected by the operation of the corresponding key-levers into the path of the indicator-wheel after the same has been moved forward past the step so that said step arrests it upon its return stroke.

12. The combination of a plurality of operating key-levers furnished on a horizontal axis, an indicator-wheel turning upon a vertical axis, a spring operating to yieldingly hold the indicator-wheel in and return it to initial position, means intermediate the wheel and key-levers for causing the operation of any one of the latter to turn the wheel from initial position, a plurality of steps adapted to be projected by the operation of the corresponding key-levers into the return-path of the indicator-wheel, means for temporarily holding the projected steps in such position, and means actuated by the key-levers for releasing the projected step upon the operation of another key-lever and projection of another step.

13. The combination of a plurality of operating key-levers furnished on a horizontal axis, an indicator-wheel turning upon a vertical axis, a spring operating to yieldingly hold the indicator-wheel in and return it to initial position, means intermediate the wheel and key-levers for causing the operation of any one of the latter to turn the wheel from initial position, a plurality of vertically-sliding stop-rods each carrying a step adapted to be projected into the return-path of the indicator-wheel when lifted by the corresponding key-lever, a movable supporting-bar cooperating with projections upon the stop-rods to hold the lifted rods in elevated position, and means intermediate said bar and the key-levers for moving the bar to release the elevated rods.

14. The combination of the key-levers A, the pivoted frame I co-operating therewith and carrying or moving the rack A', the vertical spindle E' having the pinion S' meshing with the rack A', the indicator-wheel P turning on a vertical axis, a connection between the spindle E' and wheel P by which the spindle E' turns the wheel P, the vertically-sliding rod E' carrying the steps P, the pivoted supporting bar or wing K' co-operating with projections upon the rod, and means intermediate the bar K' and levers A for disengaging the bar from the projections on the rod.

15. The combination of the key-levers A, the pivoted frame I co-operating therewith and carrying or moving the rack A', the vertical spindle E' having at its lower end with the pinion S' meshing with the rack A' and provided at its upper end with the projecting arm U' having the end V', the indicator-wheel P turning on the same vertical axis as the spindle E' and having its rod or sleeve X' provided with the arm W' co-operating with the end V' on the arm U' of the spindle E', a spring tending to hold the wheel P in initial position and return it thereon, the lever G' provided at one end with a rack meshing with the pinion S' on the wheel hub or sleeve X', and having at its opposite end the arm D' the vertically-sliding rod E' provided with the collar G' having the arm E' carrying the steps P adapted to be projected into the path of the arm D', the pivoted supporting bar or wing K' co-operating with the collar G' on the rod E', and means intermediate said bar and the key-levers A for causing the operation of the latter to disengage the bar from the collar G'.

16. In a cash-register the combination with a series of operating-levers, of a series of rotary indicators, a frame actuated by the levers for operating the indicators, a slidable connection between the frame and in-

dicator, spring means for returning said indicators when operated, and devices act by the levers for arresting the indicators at the proper points in their backward movements independently of the movements of the frame.

17. In a cash-register, the combination with a series of operating-levers, of a series of rotary indicators means moved by the levers for rotating said indicators forward, means for returning said indicators, and devices act by the levers for arresting and holding said indicators at the proper points in their backward movements while the levers return to normal position.

18. The combination of the plurality of groups of key-levers A, the two sets of indicator-wheels O' P' actuated thereby and mounted on vertical axes one above the other, the two wheels being fast upon the same spindle as to turn together, the sliding rack-bar S' meshing at its opposite ends with the pinions E' T' turning with the end wheels in opposite sets, the sliding rack-bar X' meshing at its opposite ends with the pinions T' S' upon the other end wheels of the opposite sets, and the springs W' and S' connected to the bars S' and X', respectively, whereby the upper and lower wheels of each pair are connected together and move in unison.

19. The combination of the plurality of groups of key-levers A, the indicator-wheel P co-operating with the respective groups of key-levers, the transversely-sliding cross-plate A' mounted in front of the wheel P, a spring tending to hold said plate in position to expose the numbers upon the indicator-wheel, the lever J' co-operating with said cross-plate, the universal bar or frame F' overlying the key-levers A, and the vertically-sliding rod E' pivotally connected at its lower end to the frame F' and provided at its upper end with the arm M' co-operating with the end L' upon the lever J' to shift the cross-plate A' in position to hide the indicator-wheel.

700,897. SUBALAR-ALARM. JOHN G. A. CASE, Arlington, Mass.
Filed Jan. 16, 1908. Serial No. 68,126. (No model.)

Claim.—1. In combination with a gong or bell, a striker, mechanism for actuating the striker, a housing therefor, a bent lever one arm of which is journaled in bearings attached to the housing, and provided with a catch which is adapted to engage with the striker-actuating mechanism to hold it in restraint, a spring which tends to hold the lever in a position for the catch to be disengaged when the lever is free to respond to the spring and with the unjournaled arm of said lever extending diagonally rearward beyond the rear face of the housing in such manner that when the housing is attached to a door or to one end of a window the rear end of said lever may be caused to engage with the jamb of the door or with the opposite end of the window when the door or window is closed and hold the lever against the tension of its spring in position to cause the catch to restrain the striker, said spring tending the lever and disengaging the catch when the door or window is opened, substantially as described.

2. In combination with a gong or bell, a striker, mechanism for actuating the striker, a housing therefor, a bent lever one arm of which is journaled in bearings on the housing, and provided with a catch which is adapted to hold the striker mechanism in restraint, a spring which tends to hold the lever in a position for the catch to be released, and an adjustable clamp whereby the device may be clamped to a door or to a window-cash with the free end of the lever bearing upon the door-jamb or upon the opposite window-cash while the door or window is closed thereby causing the catch to restrain the striker, the lever being freed by the opening of the door or window so that it responds to the action of the spring and releases the catch, the clamp holding the device on the door or window both when closed and open, substantially as described.

3. In combination with a gong or bell, a striker, mechanism for actuating the striker, a housing, a bent lever one arm of which is journaled in bearings in the housing, a detent on the lever which is adapted to en-

gage the striker mechanism, the unjournaled arm of the lever extending rearwardly of the housing, means for fastening the housing to the stile of a door or the rail of a window-cash, the projecting free end of the lever pressing upon the door-jamb or upon the opposite cash when the door or window is closed thereby turning the lever in its bearings and causing the detent to hold the striker in restraint, and a spring which when the door or window is opened will turn the lever in the opposite direction and release the detent, substantially as described.

4. In combination with a gong or bell, a striker, mechanism for actuating the striker, a housing, a bent lever one arm of which is journaled in bearings in the housing, a detent on the lever which is adapted to engage with the striker mechanism, the unjournaled arm of the lever extending rearwardly of the housing, means for fastening the housing to the stile of a door or the rail of a window, the projecting free end of the lever pressing upon the door-jamb or upon the opposite cash when the door or window is closed, thereby holding the lever in a position where the said detent will engage the said pin, and a spring which when the door or window is opened will turn the lever in its bearings and release the striker mechanism, substantially as described.

5. In combination with a gong or bell, a striker, mechanism for actuating the striker, a housing, a bent lever one arm of which is journaled in bearings in the housing, a detent on the lever which is adapted to engage the striker mechanism, the unjournaled arm of the lever extending rearwardly of the housing, means for fastening the housing to a door or to a window-cash, the projecting free end of the lever pressing upon the door-jamb or upon the opposite window-cash when the door is closed thereby holding the detent in engagement with the striker-actuating mechanism, and a spring which when the door or window is opened will turn the lever in the opposite direction and release the detent whereby the striker mechanism becomes operative, the closing of the door or window again setting the detent and shutting off the alarm, substantially as described.

700,898. ELECTRODES FOR ELECTRIC ACCUMULATORS. EDWARD J. CLARK, Stratford, England. Filed Jan. 4, 1908. Serial No. 68,126. (No model.)

Claim.—An accumulator-plate, consisting of a frame, a series of vertical rods crossing the same, a series of trough-shaped horizontal plates practically integral with said rods and a mass of plumbic acid held by said trough-shaped plates, the latter being rolled into said shape on said acid, thereby compressing and holding the latter substantially as set forth.

700,899. TROLLEY-WHEEL. JOHN H. CLARK, Urbana, Ohio.
Filed Sept. 11, 1901. Serial No. 74,000. (No model.)

Claim.—The combination of a trolley-wheel provided with an axle rotatable with said trolley-wheel, a trolley-band consisting of members spaced one from the other and each of the members provided with a chamber, there being a groove located in the inner face of the band members and communicating with the chambers, axle-bases located in the grooves and over the openings and means for holding the axle-bases in fixed position, substantially as and for the purposes specified.

700,900. STREET-SWEEPER. GEORGE COMBART, Goshport, N. Y.
Filed Jan. 6, 1908. Serial No. 68,126. (No model.)

Claim.—In a street-sweeper, the combination with an ordinary wagon box or body and its running-gear, of a transverse shaft journaled upon the upper rear end of said box, a swinging frame independent of the wagon frame or box and comprising side bars connected by suitable cross-pieces and mounted to swing upon the transverse shaft, the rear ends of said bars projecting beyond the rear end of the wagon-box and the front ends thereof being extended forwardly on opposite sides of the body and terminating in lever-arms, levers depending from the rear ends of the side bars, a shaft mounted in the levers and carrying a suitable brush, an endless conveyor-frame mounted to swing upon the

transverse shaft, means connecting the lower end of the conveyor-frame with the brush-shaft, whereby said conveyor-frame is mounted to swing with the sweep-frame, an endless conveyor carried by the conveyor-frame, gearing between the transverse shaft and endless conveyor for operating the latter, gearing between the transverse shaft and running-gear of the vehicle and between the brush and running-gear for driving said transverse shaft and brush, and means for engaging the lever-arms when the latter are depressed to hold the swinging frame and brush mechanism elevated, substantially in the manner described.

700,901. PRUNING IMPLEMENT. ALFRED CHASE OF ALBANY, N. Y.
Filed Oct. 16, 1901. Serial No. 75,000. (No model.)

Claim.—1. In a pruning implement, a lanceolate-shaped frame having a space at its lower end for the reception of the branch or part to be removed, and oppositely-disposed cooperating rotary cutters journaled to the side bars of the frame at their point of flexure, substantially as set forth.

2. In a pruning implement, a frame composed of side bars each comprising oppositely-inclined parts, said bars being joined at their upper ends and spaced apart at their lower ends, and one of the side bars being extended to form a chuck, a pole attached to the said chuck, and oppositely-disposed cooperating rotary cutters journaled to the side bars at their point of flexure substantially as set forth.

3. In a pruning implement, a head or frame of lanceolate shape composed of spaced complementary side members or parts, filling-pieces secured between the said members, and oppositely-disposed cooperating rotary cutters located in the space between the side bars of the said members, substantially as specified.

4. The herein-described pruning implement comprising a pole or shaft, a lanceolate-shaped head or frame composed of spaced side members or parts, each composed of side bars having portions oppositely inclined, the bars being spaced at one end and one set of bars having extensions forming chucks embracing opposite sides of the pole and secured thereto and having other portions to extend over the upper end of the pole, filling-pieces secured between the members or parts, and cooperating rotary cutters journaled between the side bars of the head at the angle formed between the oppositely-inclined parts, substantially as specified.

700,902. MOTOR-VEHICLE FRAME. WALTER A. CHURCH.
Chicago, Ill. Filed June 23, 1901. Serial No. 65,942. (No model.)

Claim.—1. A vehicle-frame comprising front and rear axle supports, upwardly-extending arms thereon, side bars connecting said arms on said axle-supports and struts or braces which connect said side bars with said axle-supports, substantially as described.

2. A vehicle-frame comprising front and rear axle supports, upward and downward projections thereon, side bars which connect said upward projections and struts or braces which connect said side bars with the downward extensions of said axle-supports, substantially as described.

3. A vehicle-frame comprising front and rear axle supports, upward projections thereon, downward projections thereon outside of said upward projections, side bars which connect the upward projections on said front and rear axle supports and struts or braces which connect said side bars with the downward projections of said axle-supports, substantially as described.

4. In a vehicle-frame, the combination of an axle-support, an axle pivoted thereto, downward projections on said axle-support provided with vertically-disposed slots which embrace said axle, a side of each of said slots being formed by a plate removably secured to said axle-support, substantially as described.

5. A vehicle-frame comprising front and rear axle supports, upwardly-extending arms thereon, side bars which connect said arms and springs hung from said arms, substantially as described.

6. A vehicle-frame comprising front and rear axle supports, side bars which connect said axle-supports, upward projections on said axle-supports, springs hung from said upward projections, the relation of parts being such that the tops of said springs are substantially on a line with the points of connection to said upward projections on said axle-supports, substantially as described.

7. A vehicle-frame comprising front and rear axle supports, upward projections thereon and springs hung from said upward projections, the relation of parts being such that the tops of said springs are substantially on a line with their points of connection to the upward projections on said axle-supports, substantially as described.

8. A vehicle-frame comprising front and rear axle supports, side bars which connect said axle-supports, an axle pivoted to the front-axle support, downward projections on said front-axle support provided with vertically-disposed slots which embrace said axle and struts or braces which connect said side bars with the downward projections on said front-axle support, substantially as described.

9. A vehicle-frame comprising front and rear axle supports, upward projections thereon, rigid connection between said front and rear axle supports, an axle pivoted to said front-axle support, guides on said front-axle support which embrace said axle and springs hung from the upward projections on said front and rear axle supports, substantially as described.

10. The combination with an axle-support provided with spherically-grooved openings, bearing-bones provided with grooves in their external surfaces, the bottoms of said grooves forming sections of spheres fitted to and adapted to be secured in the spherically-grooved openings in said axle-support, the portions of said axle-support which enter said grooves in said bearing-bones being thinner than the width of said grooves and an axle mounted in said bearing-bones, substantially as described.

700,903. GARMENT. BASIL BROWN, New York, N. Y. Filed Dec. 23, 1901. Serial No. 65,943. (No model.)

Claim.—1. A garment having a waist-closure formed with openings at the sides, overlapping flaps at said openings, means for drawing the

flaps one above the other to take up slack at the waist without bunching or puckering and means for holding the inner flap up in position, substantially as described.

2. A garment having a waist-closure formed with side openings, overlapping flaps at said openings, and means for adjusting or drawing in the waist at the said openings, said means having a yielding portion insuring a snug fit, the flaps preventing any puckering or bunching of the garment at these points, substantially as described.

3. A garment having a waist-closure formed with side openings, inner and outer flaps at said openings, means for holding the inner flap from dropping or sagging out of position, and means attached to the outer flap for taking in any slack in the waist portion of the garment and adjusting it to suit the person of the wearer of the garment, substantially as described.

4. A garment having a waist-closure formed with side openings, inner and outer flaps arranged at these openings, a yielding connection joining the inner flap and the inner face of the outer flap for yieldingly holding the said inner flap in position and permitting said flap to accommodate itself to the adjustment of the outer flap, and means for adjusting the outer flap to draw the waist of the garment snugly about the body of the wearer, substantially as described.

5. A garment having a waist portion formed with openings having inner and outer flaps, a yielding strap secured to the inner flap at one end and extending between the lining and goods of the outer flap where it is attached at its other end to the said outer flap, and means for adjusting the outer flap so as to take up slack in the waist, the yielding strap of the inner flap accommodating itself to such an adjustment and maintaining the parts in a smooth position, substantially as described.

6. A garment having a waist portion with side openings formed therein, inner and outer flaps at the said openings, the outer flaps overlying the inner flaps to a considerable extent, a yielding means for holding the inner flap in proper position so as not to pucker or wrinkle beneath the other flap, and a yielding means for holding the outer flap in proper position, substantially as described.

7. A garment having a waist portion formed with side openings, inner and outer flaps arranged at these openings, an elastic strap secured to the inner flap and connecting it with the inner face of the outer flap, a strap secured to the outer flap, a buckle or other fastening for engaging said strap, a yielding means connecting said buckle with the goods of the trousers, the inner yielding straps yielding in correspondence with the adjustment of the outer yielding buckle connection, substantially as described.

8. A garment having a waist-closure formed with suitable openings, inner and outer flaps at said openings, means for opening the outer flaps in place, and bands or straps for covering the inner flaps in position corresponding always with the adjustments and arrangement of the outer flaps, substantially as described.

9. A garment having a waist-closure having an opening, inner and outer flaps covering the opening, an elastic connection joining the inner flap with the opposite side of the opening, and means for adjusting the outer flap.

10. A garment having a waist-closure having an opening, inner and outer overlapping flaps covering the opening, elastic connection joining the inner flap to the opposite side of the opening, and elastic means for adjusting the outer flap.

11. A garment having a waist-closure having side openings, inner and outer overlapping flaps covering each opening, an elastic connection joining the inner flap to the opposite side of each opening, and elastic means for adjusting the outer flap.

700,904. GRAVE-MARKER. JAMES A. DELANEY, Chicago, Ill.
Filed Aug. 12, 1901. Serial No. 72,974. (No model.)

Claim.—1. A device of the class described, comprising a front plate

having an aperture extending entirely through it, a transparent pane covering the aperture, and a back plate fitting within the aperture and adapted to secure a card in the same, and provided with arms extending beyond the aperture and detachably fastened to the front plate, said back plate being provided with a rearwardly-extending leg adapted to receive a post or support, substantially as described.

2. A device of the class described comprising a front plate having an aperture and provided at its back with a recess surrounding the aperture and having an angular inner portion and a beveled outer portion, a holder adapted to receive a card and arranged in the angular inner portion of the recess, a beveled back plate fitting within the beveled portion of the recess and provided with extensions, fastening devices detachably securing the extensions of the back plate to the front plate, and a post or support, substantially as described.

700,905. RAY-STACKER. SILVSTER C. DUNHAM, Vol. Ives.
Filed Oct. 12, 1899. Serial No. 22,985. (No model.)

Claim.—A ray-stacker comprising a ground-frame composed of a pair of runners disposed on converging lines, cross-bars rigidly connecting the runners, a shaft mounted in bearings on the upper side of the runners at the wide end thereof, a fork-frame secured to the shaft on the outer side of the runners and provided at its upper end with a fork comprising fixed and movable flaps, a guy-rope secured to the center portion of the ground-frame and to the fork-frame, a shaft mounted in bearings in the upper side of the runners near the center thereof, a rocking frame carried by the shaft and disposed on the inner side of the runners and of the fork-frame, a cross-bar carried by the fork-frame on which the said rocking frame is adapted to bear, ropes secured to the opposite side portions of the front end of the rocking frame and the upper portion of the fork-frame, and operating-rope having their ends secured to the upper portion of the rocking frame and extended laterally from one side of the front end of the ground-frame and passed alternately through pulleys on the front end of the latter frame and the upper end of the rocking frame, substantially as and for the purpose specified.

700,908. TYPE-WRITING CLAVIER. CHARLES HOWARD, Brooklyn, N. Y. Filed Sept. 12, 1901. Serial No. 73,383. (No model.)

Claim.—1. A type-writing clavier, comprising a series of key-levers and sounding mechanism common to all of said series of key-levers and adapted to be actuated by any one of them.

2. A type-writing clavier, comprising a series of key-levers, and a spring-clicker adapted to be operated by any key-lever of the series and to sustain the force of a blow on the keys.

3. A type-writing clavier, comprising a casing, key-levers supported therein, a copy-holding bracket comprising a yoke having its arms pivoted to the ends of the casing and adapted to be folded down and surround the key-levers, and a stop on the end of the casing for holding the bracket in position to support a copy.

4. A type-writing clavier, comprising a casing, key-levers supported therein, a copy-holding bracket pivoted at its ends to the ends of the casing, a stop projecting from the casing for holding the bracket in an inclined position and a plate or rest upon the casing and cooperating with the bracket to support a copy.

5. In a type-writing clavier, the combination with a frame or cradle, of a key-lever mounted in said cradle, a spring-clicker operated by the lever when depressed and a spring normally holding the lever out of engagement with the clicker.

6. In a type-writing clavier, the combination with a frame or cradle, of a shaft secured in said cradle, key-levers fulcrumed near their ends on the shaft, springs holding the long ends of the levers elevated and a platform on the cradle supporting the short ends of the levers and allowing the keys on the long ends of the levers.

7. In a type-writing clavier, the combination with a frame or cradle, of a shaft secured in said cradle, a series of key-levers fulcrumed near their inner ends on said shaft, springs holding the long ends of the levers elevated, a platform limiting the downward movement of the short ends of the levers and means allowing the keys on the long ends of the levers, and adjustable means for limiting the depth of movement of the keys.

8. In a type-writing clavier, the combination with a frame or cradle, of a shaft secured in said cradle, a series of key-levers fulcrumed near their inner ends on said shaft, springs holding the long ends of the levers elevated, an aligning-platform limiting the downward movement of the short ends of the levers, and a stop adjustably secured to the cradle and adapted to limit the upward movement of the short ends of the levers.

9. In a type-writing clavier, the combination with a frame or cradle, of a key-lever fulcrumed near its inner end in said cradle, a rod extending transversely above said lever, a transverse bar on the cradle in rear of said rod, a spring bearing between its ends on said rod, its short end disposed beneath the bar and its long end bent at right angles and provided with a hook engaging the lower edge of the long end of the key-lever.

10. In a type-writing clavier, the combination with a cradle, and a series of key-levers fulcrumed near their inner ends therein, of a spring-clicker secured to the cradle beneath the key-levers, a frame secured to the cradle and limiting the upward movement of the clicker, a rod bent at its ends and pivotally secured to the cradle, springs holding said rod against the lower edge of the levers and individual springs holding the several key-levers above the clicker.

11. In a type-writing clavier, the combination with a cradle, and a series of key-levers fulcrumed near their inner ends therein, of a spring-clicker secured to the cradle beneath the key-levers, a rod bent at its ends and pivotally secured to the cradle and adapted to operate the clicker when a key-lever is operated, springs holding said rod against the lower edge of the levers, individual springs holding the several key-levers elevated and one of said key-levers arched or bowed to avoid contact with the rod.

12. In a type-writing clavier, the combination with a series of key-levers, of a bell, and means intermediate of the bell and one of the key-levers for sounding the bell only when said key-lever is depressed.

13. In a type-writing clavier, the combination with a casing and a series of key-levers supported therein, of a bell in said casing, a spring-lever in said casing, a knocker on one end of the spring-lever, and a flak connecting the other end of said spring-lever with one of said key-levers.

14. In a type-writing clavier, the combination with a casing, of key-levers supported in the casing, spacing-bar levers also supported in the casing and carrying a spacing-bar, a dial on the casing, a ratchet-wheel for turning the dial to register with a fixed pointer, a lever fulcrumed between its ends in the casing, a dog on one end of the casing to turn the ratchet-wheel a distance of one tooth each time the lever is operated, and a link connecting the other end of the lever with one of the spacing-bar levers.

15. In a type-writing clavier, the combination with a casing of a frame therein, a shaft supported in the frame and projecting through the casing, a dial secured on the shaft in front of the casing, a ratchet-wheel on the shaft in the casing, a spring friction-brake engaging said shaft, a lever fulcrumed between its ends in said casing, a pivoted dog carried by one end of the lever and in engagement with the teeth of the ratchet-wheel, a spacing-bar lever projecting out of the casing and a link connecting said levers.

16. In a type-writing clavier, the combination with a casing, of a frame therein, a shaft supported in the frame and projecting through the casing, a dial secured on the shaft in front of the casing, a fixed pointer registering with the dial, a ratchet-wheel on said shaft in the casing, a dog for turning said wheel, a spacing-bar for operating said dog, another dog for preventing the turning of the ratchet in but one direction and a button on the center of the dial for manually turning the same.

700,907. HAT-REST. GEORGE EDWARDS and JOHN EDWARDS, Stockport, England. Filed Apr. 26, 1901. Serial No. 87,095. (No model.)

Claim.—1. In a hat-rest, the pillar *a*, the hat-supporting rings *d* formed with the forked arm ends *e* directly pivotally connected to the said pillar and the springs *f* secured to the latter adjacent to the said forked ends, the said forked ends being cranked to bear against the said pillar and the said springs to engage and retain the said hat-rings in their lowered and raised position respectively, all combined substantially as and for the purpose set forth.

2. In a hat-rest having the pillar *a* and the hat-supporting rings *d* with the forked ends *e* directly pivotally connected to the said pillar, the cockets *g* on the said forked ends, the pin *h* on the ring-arm *c*, received by the said cocket, and means for rotarily adjusting the latter in the said cocket to allow of tilting the said hat-rings, all combined substantially as and for the purpose set forth.

3. In a hat-rest having the pillar *a* and the hat-supporting rings *d* with forked ends *e* directly pivotally connected to the said pillar, the pivots *i* on the said forked ends receiving the said ring-arms and the springs *f* secured to the said pillar adjacent thereto, the said pivot allowing the said hat-rings to be moved laterally and the said springs serving to engage and hold the same in position, all combined substantially as and for the purpose set forth.

700,908. ACETYLENE-GAS GENERATOR. ALFRED C. BISHOP, St. Louis, Mo. Filed June 5, 1901. Serial No. 88,178. (No model.)

Claim.—1. In an acetylene-gas generator, the combination of a generator-tank, a carbide-holder, a feed-valve arranged to control the out-

let from said carbide-holder, a spring-pressed diaphragm having connection with said feed-valve and subject to pressure from the gas in said generator-tank, a gasometer arranged in communication with said generator-tank, a gas-receiving pipe in said gasometer, a water-seal member mounted on said gas-receiving pipe, a gasometer-bell and means to elevate the water-seal member on the descent of the bell and permit it to descend on the rise of the bell, whereby a constant gas-pressure is maintained in the bell and the gas-pressure in the generator, by which the diaphragm is operated, varies according to the amount of gas in the bell.

2. In an acetylene-gas generator, the combination with a generator comprising a tank and a carbide-holder, of a feed-valve arranged to control the outlet from said carbide-holder, a spring-pressed diaphragm having connection with said feed-valve and subject to pressure from the gas in said generator-tank, a gasometer arranged in communication with said generator-tank, a gas-receiving pipe in said gasometer, a water-seal member mounted on said gas-receiving pipe, a pivoted lever connected in said member and a gasometer-bell arranged to engage said lever on the descent of the bell and permit it to descend on the rise of the bell, whereby a constant gas-pressure is maintained in the bell and the gas-pressure in the generator, by which the diaphragm is operated, varies according to the amount of gas in the bell.

700,909. FOUNTAIN-PEN. WILLIAM S. FRASER, New York, N. Y., assignor to Fraser & Geyer Co., New York, N. Y., a Corporation of New York. Filed July 18, 1901. Serial No. 88,711. (No model.)

Claim.—1. In a fountain-pen, the combination with the barrel or casing, of a rotary pen-operating member mounted within the upper open end of the barrel and having its outer end within the plane of, but exposed through, the said open end, the said outer end of the rotating member being shaped to receive a separate and independent rotating device.

2. In a fountain-pen, the combination with the barrel or casing, of a rotary pen-operating member mounted within the upper open end of the barrel or casing and having its outer end within the plane of, but exposed through, the said open end, a removable cap for the lower end of the casing or barrel and interlocking connections for separably connecting the cap and the said upper end of the rotary member for rotating the latter; substantially as described.

3. In a fountain-pen, the combination with the barrel or casing, of a rotary pen-operating member mounted within the upper end of the barrel or casing and having a socket in its outer end accessible through the upper open end of the said casing or barrel, and a removable cap for the lower end of the casing or barrel having a nipple of a size to snugly fit said socket and form a frictional connection therewith; substantially as described.

4. A fountain-pen comprising the barrel or casing, a pen-carrying rod or member therein, a tubular crown-plug forming the upper end of the barrel or casing, a spirally-grooved head operatively connected with the pen-carrying rod and provided with a shank having a rotary operating member lying wholly within the outer end of said tubular plug and provided in its outer end with a conical socket, and a cap removably fitting the lower end of the barrel or casing and provided with a conical nipple to frictionally engage the said socket and rotate the spirally-grooved head; substantially as described.

5. In a fountain-pen, the combination with the barrel or casing provided at its lower end with a removable cap, of a rotary operating member wholly within the upper end of the barrel, but exposed through the upper end thereof, and means for frictionally connecting the said removable cap with the said rotary operating member and comprising a nipple and socket shaped for frictional engagement, whereby when the said co-

coupling member has been sufficiently rotated the connection between it and the cap will slip; substantially as described.

700,910. PITMAN CONNECTION. JOHN CLINE, Kenton, Ohio.
Filed Dec. 22, 1901. Serial No. 84,908. (No model.)

Claim.—A pitman-rod having an articulate coupling comprising a coupling member having a socket formed with teeth, a yoke whose jaws are provided with beaks to engage said teeth, one of said jaws being fixed and the other pivoted, and a belt passing through the beaks and teeth, substantially as described.

700,911. SIGNAL FOR COMPOSITE TELEGRAPHIC AND TELEPHONE TRANSMISSION. EDWIN L. GRAHAM, Carthage, N. Y. Filed Jan. 24, 1902. Serial No. 91,000. (No model.)

Claim.—1. The method of transmitting intelligence which consists in superposing on a current of fixed direction an unidirectional pulsating current, thereby unbalancing the current of fixed direction in one half and reinforcing it on the other half of the circuit, substantially as specified.

2. The method herein described for signaling which consists in superposing upon a current, a current which compounds or acts in conjunction with the first-named current to effect a signal, substantially as specified.

3. The method herein described for signaling which consists in superposing upon a current a current acting in opposition thereto, substantially as and for the purpose specified.

4. The method herein described for signaling on a current of fixed direction, the same consisting in superposing thereon a direct pulsating current of such slow frequency as will operate the line-relays, substantially as specified.

5. The method herein described for signaling on a current of fixed direction, which consists in superposing thereon a direct pulsating current of opposite direction, substantially as and for the purpose specified.

6. The method herein described for signaling on a current of fixed direction, which consists in superposing thereon a direct pulsating current without impairing the integrity of the line-wire of the current of fixed direction, substantially as specified.

7. The method herein described for changing the direction of the signal, said signal being produced by superposing a direct pulsating current upon a current of fixed direction, which consists in reversing or changing the direction of the direct pulsating current.

8. The method herein described for signaling over a circuit normally energized by current of fixed direction, which consists in directing over said circuit in multiple relation therewith, intermittently-transmitted direct currents, and thereby unbalancing one portion of said circuit, substantially as specified.

9. The method herein described for signaling over a telegraphic circuit, which consists in directing over said circuit in multiple relation therewith intermittently-transmitted direct currents, and thereby unbalancing one portion of said circuit, substantially as specified.

10. The method for signaling over a telegraphic circuit, which consists in directing over said circuit in multiple relation therewith, intermittently-transmitted direct currents of either polarity, and thereby unbalancing alternative portions of said circuit, substantially as specified.

700,912. SIGNALING AND TELEPHONING APPARATUS. EDWIN L. GRAHAM, Carthage, N. Y. Filed Jan. 24, 1902. Serial No. 91,100. (No model.)

Claim.—1. The combination in a signaling and telephoning apparatus, of a receiver-circuit, a generator-circuit, and means common to both circuits for detachably connecting said circuits with a telegraph-line wire without impairing the integrity of said line-wire; substantially as and for the purpose specified.

2. The combination in a signaling and telephoning apparatus, of a transmitter-circuit, a receiver-circuit having a condenser interposed therein, a generator-circuit, and means common to all of said circuits for detachably connecting said circuits with a telegraph-line wire without impairing the integrity of said line-wire; substantially as and for the purpose specified.

3. The combination in a signaling and telephoning apparatus, of a receiver-circuit having a condenser interposed therein, a generator-circuit, means for merging said circuits in a single circuit adapted to connect said circuits with a telegraph-line, and a reel for reeling up said connecting-wire, substantially as and for the purpose specified.

4. In a signaling and telephoning apparatus, the combination of a transmitter-circuit, a receiver-circuit, and a generator-circuit, a receiver-hook having a hook-switch common to all of said circuits, a receiver, and a receiver-lock, whereby the receiver is held, and the common switch controlled when the receiver is in position on its hook, substantially as specified.

5. The combination with the transmitter-circuit and the receiver-circuit, of a receiver-hook having a hook-switch common to said circuits, a receiver, and a receiver-lock which holds the receiver and controls the hook and hook-switch when the receiver is in position on the hook, substantially as and for the purpose specified.

6. In a signaling and telephoning apparatus, the combination with signaling and telephoning circuits, of a single connection common to said circuits, and a circuit-pole provided with a snap or clamp adapted to electrically connect the same with a telegraph-wire, substantially as and for the purpose specified.

700,918. STITCH-SEPARATING MACHINE. JOHN R. HADWAY, Brockton, Mass. Filed June 2, 1901. Serial No. 68,798. (No model.)

Claim.—1. A stitch-separating machine, having, in combination, two indenting-tools arranged to operate on opposite sides of the work, means co-operating with the stitches to determine the location of the indentations and means for actuating the tools to indent the work, substantially as described.

2. A stitch-separating machine, having, in combination, two indenting-tools arranged to operate on opposite sides of the work, means for adjusting the tools for operation upon work of different thicknesses, and means for positively actuating the tools to indent the work, substantially as described.

3. A stitch-separating machine, having, in combination, two indenting-tools arranged to operate on opposite sides of the work, and means controlled by the thickness of the work for positively actuating the tools to produce indentations of the same depth in work of different thicknesses, substantially as described.

4. A stitch-separating machine, having, in combination, two indenting-tools arranged to operate on opposite sides of the work, means controlled by the work for automatically adjusting the tools for operation upon work of different thicknesses, and means for actuating the tools to indent the work, substantially as described.

5. A stitch-separating machine, having, in combination, two indenting-tools arranged to operate on opposite sides of the work, one of said tools acting to move the work into position to be acted upon by the other tool, and means for actuating the tools, substantially as described.

6. A stitch-separating machine, having, in combination, two indenting-tools arranged to operate on opposite sides of the work, means for locating each tool in a stitch interval whether the stitches are of uniform or varying length and means for actuating the tools to indent the stitch intervals, substantially as described.

7. A stitch-separating machine, having, in combination, two indenting-tools arranged to operate on opposite sides of the work, means for actuating one tool to indent and feed the work, means for locating the other tool in a stitch interval during the feeding of the work, and means for actuating said tool to indent the work, substantially as described.

8. A stitch-separating machine, having, in combination, an indenting-tool arranged to operate on one side of the work, a yieldingly-mounted work-support, an indenting-tool mounted on said work-support arranged to operate on the opposite side of the work, means for actuating the tools to indent the work and means for locking the work-support during the indenting action of the tools, substantially as described.

9. A stitch-separating machine, having, in combination, two indenting-tools arranged to operate on opposite sides of the work, acting successively to form indentations therein, and means for actuating the tools, substantially as described.

10. A stitch-separating machine, having, in combination, two indenting-tools arranged to operate on opposite sides of a finished seam, means for locating each tool in a stitch interval whether the stitches are of uniform or varying length and means for actuating the tools to indent said intervals, substantially as described.

11. A stitch-separating machine, having, in combination, a combined indenting and feeding tool located on one side of the work and an indenting-tool located on the opposite side of the work, and mechanism for actuating the tools, substantially as described.

12. A stitch-separating machine, having, in combination, a tool acting on the stitches to feed the work and an indenting-tool located on the

opposite side of the work and movable with the work, and means for actuating the tools, substantially as described.

13. A stitch-separating machine, having, in combination, a combined indenting and feeding tool located on one side of the work, an indenting-tool located on the opposite side of the work, means for yieldingly holding the indenting-tool against the work during a portion of the feeding movement, and means for actuating the tools, substantially as described.

14. A stitch-separating machine, having, in combination, an indenting-tool, a tool-carrier mounted to slide in the direction of the feed by the engagement of the work with the tool, means for holding the tool yieldingly against the work, means for feeding the work, and means for actuating the tool to indent the work, substantially as described.

15. A stitch-separating machine, having, in combination, two indenting-tools arranged to operate on opposite sides of a finished seam, and means for actuating the tools to indent the intervals between the stitches and to feed the work, substantially as described.

700,914. HYDROCARBON-BURNER. JOHN F. HARTY, Montreal, Ind. Filed Oct. 18, 1900. Serial No. 68,801. (No model.)

Claim.—1. A hydrocarbon-burner comprising a body portion provided with a mixing-chamber, a supply-pipe and an injector-tube, the latter discharging into the mixing-chamber, said body portion embracing a rising shell which surrounds the upper part of the mixing-chamber, the wall of said shell being provided with a passage which extends at its upper end near the point of combustion and communicates with the injector-tube, and said supply-pipe having a tubular part which enters a second passage in the wall of said shell and terminates adjacent to the point of combustion of the burner, said second passage being constructed to provide outside of the tubular part a conduit which communicates with the first-mentioned passage and through which with the injector-tube, and the tubular part communicating at its upper end with said conduit, and said supply-pipe fitting detachably within an opening in the body portion, and the tubular part being connected with the supply-pipe so as to be removable therefrom from the body portion.

2. A hydrocarbon-burner comprising a body portion provided with a centrally-located mixing-chamber, a supply-pipe and an injector-tube, the latter discharging into the mixing-chamber, said supply-pipe having a tubular part which enters a vertical passage formed in the wall of the mixing-chamber and terminating adjacent to the point of combustion of the burner, said passage being constructed to provide outside of the tubular part a conduit which communicates with the injector-tube, the tubular part communicating at its upper end with said conduit and the passage having a roughened interior to increase its radiating-surface.

3. A hydrocarbon-burner comprising a body portion provided with a mixing-chamber, a supply-tube and an injector-tube, which latter discharges into said mixing-chamber, said body portion embracing a rising shell which surrounds the upper end of the mixing-chamber and said supply and injector tubes communicating with each other through the medium of a tortuous vaporizing and superheating passage formed in the wall of said shell and embracing two similar parts, each consisting of an outer and an inner passage which have communication with each other at the upper ends thereof and the two parts of the tortuous passage communicating with each other near the lower ends thereof through an opening formed in the body of the burner.

4. A hydrocarbon-burner comprising a body portion provided with a mixing-chamber, a supply-tube and an injector-tube, the latter discharging into the mixing-chamber, said body portion embracing a rising hollow shell which surrounds the upper part of the mixing-chamber, said shell being provided in its wall with upwardly-directed passages which terminate adjacent to the point of combustion of the burner, and the supply and injector tubes having tubular parts which enter said passages and communicate at their upper ends with conduits formed in the passages and surrounding the tubular parts, said conduits being connected by a communicating passage.

5. A hydrocarbon-burner comprising a body portion provided with a mixing-chamber, a supply-tube and an injector-tube, which latter discharges into said mixing-chamber, said supply and injector tubes communicating with each other through the medium of a tortuous vaporizing and superheating passage, said passage embracing two similar parts, each consisting of an outer and an inner passage which have communication with each other at their upper ends, and one of which is provided with a roughened inner wall, the two parts of the tortuous passage communicating said each other near the lower ends thereof.

6. A hydrocarbon-burner comprising a body portion provided with a mixing-chamber, and with a passage extending at its upper end near the point of combustion, an injector-tube discharging into the mixing-chamber and communicating at its end remote from the mixing-chamber with said passage, and a supply-pipe fitting detachably within an opening in the body portion and provided with a reduced part which enters a passage in the body portion, said reduced part being connected with the supply-pipe and located in alignment therewith so as to be removable from the body portion with said pipe and communicating at its upper end near the point of combustion with said passage, and the passage communicating at its lower end with the first-mentioned passage and the injector-tube.

7. A hydrocarbon-burner comprising a body portion provided with a mixing-chamber, an injector-tube discharging into the mixing-chamber, said body being provided with a supply-passage which terminates near the point of combustion and adapted for connection with a supply-pipe, and the injector-tube being provided at its upper end with a reduced portion which enters a second elongated passage in said body and is located concentrically therein, said reduced portion communicating at its upper end near the point of combustion with said second passage, and said second passage communicating through a small connecting-passage with the supply-passage of the burner.

8. A hydrocarbon-burner provided with a mixing-chamber, a supply-pipe and an injector-tube, the latter discharging into the mixing-chamber, said injector-tube having a reduced part which enters a passage formed in the wall of the mixing-chamber and terminates adjacent to the point of combustion of the burner, said passage being constructed to provide outside of the tubular part a conduit which communicates with the supply-pipe, the tubular part communicating at its upper end with said conduit and said passage having a roughened inner wall.

9. A hydrocarbon-burner comprising a body portion provided with a mixing-chamber, and with a passage extending at its upper end near the point of combustion, an injector-tube discharging into the mixing-chamber and communicating at its end remote from the mixing-chamber with said passage, and a supply-pipe communicating with a reduced part which enters a second passage in the body portion, said reduced part communicating at its upper end near the point of combustion with said second passage and said second passage communicating at its lower end with the first passage and through which with the injector-tube.

10. The combination with the body of a hydrocarbon-burner provided with an annular depending shell or jacket, which latter is provided in its wall with an opening, of a plate curved to conform to the curved surface of said jacket adapted to close said opening, said plate depending loosely from a support projecting from the jacket, whereby it is swung by its weight to its lowermost position, and means on said support acting when the plate is swung downwardly to move the same closely against the jacket-wall.

11. The combination with the body of a hydrocarbon-burner provided with an annular depending shell or jacket, which latter is provided in its wall with an opening, of a curved plate pivoted to a support projecting from the jacket, and a conical projection on the support radially outside the plate with respect to the axis of the jacket, the pivot-opening in the plate being made larger than the pivot-support inside said conical projection whereby, when the plate is swung upwardly, the pivoted end thereof moves outwardly and outwardly over said conical projection, said plate when released swinging downwardly by gravity into its closing position, and the conical projection causing the plate to be moved inwardly against the jacket-wall.

12. The combination with the body of a hydrocarbon-burner provided with a supply-pipe, and a flange or jacket depending from the body, which latter is provided with a slot to pass over said supply-pipe, of a plate depending loosely from said supply-pipe adapted to cover said slot and curved to correspond to the outer curved surface of said flange or jacket, said plate being free to swing to its lowermost position by its own weight when released, and means on said support acting when the plate is swung downwardly to move the plate closely against said jacket.

13. A hydrocarbon-burner comprising a body portion provided with a mixing-chamber, a supply-tube and an injector-tube connected with vaporizing and superheating passages in said body portion, said injector-tube discharging into the mixing-chamber, an auxiliary heating-coil located below the said injector-tube and provided with a wick comprising a wire covered with an absorbent material and coiled in spiral form.

14. A wick for the purpose set forth and comprising a wire covered with an absorbent material and coiled in spiral form.

15. A wick for the purpose set forth comprising a wire covered with an absorbent material, said wick being coiled in spiral form and shaped into a ring.

700,915. WICKS FOR LAMP AND TEXTILE FANES. EDWARD HARTMAN, Rochester, Penna. Filed Apr. 9, 1901. Serial No. 68,802. (No specimen.)

Claim.—1. A fabric adapted to produce a voltaic action by contact with the human body, comprising threads made of textile material twisted with an electropositive metal, threads made of textile material twisted with an electronegative material, and pure textile threads isolating the electropositive material from the electronegative.

2. A fabric adapted to produce a voltaic action by contact with the human body, comprising threads made of textile material twisted with aluminum threads made of textile material twisted with copper, and pure textile threads isolating the electropositive material from the electronegative.

700,916. FILTER. CHARLES E. HARTMAN, Wheeling, Pa. Filed July 9, 1901. Serial No. 67,848. (No model.)

Claim.—1. In a filter, the combination with a casing divided by a partition into two chambers one for filtered and the other for unfiltered water, a screened opening in said partition, a receptacle for filtering material secured to partition below the screened opening therein and a series of absorbent sheets removably secured over said screened opening.

2. A filter comprising a water-chamber having a bottom therein, filtering material supported by said bottom and chains or cords secured to the upper end of the filter and hooks on the free ends of said chains or cords to hook over the edge of a receptacle and support the filter.

3. In a filter, the combination with a water-chamber having a bottom with an opening therein covered by a screen, of a ring secured on said bottom around the opening therein, a series of sheets of absorbent in said ring, a clamping-ring securing a cloth covering over said absorbent sheets, a screw-threaded ring secured around the opening on the under side of the bottom, and a receptacle for filtering material secured onto said last-mentioned ring and having convex wire-mesh bottom.

4. A filter comprising a receptacle for unfiltered water, means therein for filtering the water, and chains secured to the top of the filter and hooks on the chains for supporting the filter in a receptacle.

700,917. BED-BRACE. JOHN E. HARTMAN, Adams, Pa. Filed Dec. 11, 1901. Serial No. 68,810. (No model.)

Claim.—1. In a brace of the class described, the combination of a relatively fixed member having means to engage a beam-rod, a revol-

lin cam member detachably mounted on the fixed member, said cam member having peripheral brace-wire-engaging means, and means to lock the revolvable cam member against reverse rotation, substantially as described.

2. In a brace of the class described, the combination of a relatively fixed member having means to engage a brace-wire, a revolvable cam member detachably mounted on the fixed member, said cam member having peripheral brace-wire-engaging means, means to lock the revolvable cam member against reverse rotation, and a lever to operate said cam member, the lever and the lever having mutually-engaging means to detachably secure the lever to the cam member, substantially as described.

3. A brace comprising a hook member having a slot extending through the greater portion thereof and provided with hooks at one end, a cam member adapted to extend into said slot between said hooks, one of said hooks being provided with means for engaging the upper face of said cam member.

4. A brace comprising a hook member having a slot extending through one end thereof, hooks disposed on said divided end, a spring-actuated dog extending through the shank of one of said hooks and projecting into said slot, a cam member journaled in said hooks and having match-teeth adapted to be engaged by said dog.

5. A brace comprising a hook member having a slot extending through one end thereof, hooks disposed on said divided end, a spring-actuated dog extending through one of said hooks and projecting into said slot, a cam member disposed in said slot and journaled in said hooks, ratchet-teeth disposed on said cam member and adapted to be engaged by said dog, catches in said cam member, and means for engaging said catches for rotating said cam member.

700,918. CORBET-STRELL. ALVIN A. HARVEY, Birmingham, N. Y.
Filed May 15, 1901. Serial No. 69,343. (No model.)

Claim.—A corset-steel of the usual construction, having a reinforcement of rubber connected its entire length to the central portion of the steel so as to be immovable thereon, the reinforcement being of a greater thickness than the steel so as to render the same bendable therewith when said steel and rubber come together, substantially as specified.

700,919. COMPUTING-SCALE. ARTHUR B. HAYDEN, Chicago, Ill., assignor to Computing Scale Company of America, a Corporation of New Jersey. Filed Sept. 8, 1900. Serial No. 739,576. (No model.)

Claim.—1. In a spring-balance computing-scale, the combination of a suitably-supported vertical non-rotatable casing provided with a price-index, a vertical rotatable computing-cylinder journaled in said casing, provided with cost computations, a spring-supported lead-bearing and cylinder-revolving rod suspended from said casing, and connecting means between rod and computing-cylinder, whereby by longitudinal movement of the rod rotary movement is imparted to said cylinder, substantially as and for the purpose set forth.

2. In a spring-balance computing-scale, the combination of a suitably-supported vertical non-rotatable casing provided with a price-index, a vertical rotatable computing-cylinder journaled in said casing, provided with cost computations, a spring-supported lead-bearing and cylinder-revolving rod non-rotatably suspended from said casing, and connecting means between said rod and computing-cylinder, whereby longitudinal movement of the rod produces rotary movement of the cylinder, substantially as and for the purpose set forth.

3. In a spring-balance computing-scale, the combination of a suitably-supported vertical non-rotatable casing provided with a price-index,

a vertical rotatable computing-cylinder journaled in said casing, provided with cost computations, a spring-supported lead-bearing and cylinder-revolving rod non-rotatably suspended from said casing, said rod being provided with a spiral, and rollers journaled in said cylinder and engaging said spiral, whereby longitudinal movement of the rod turns the cylinder, substantially as and for the purpose set forth.

4. In a spring-balance scale, a suitably-supported non-rotatable casing provided with a vertical slot, a price-index on a margin of said slot, a vertical computing-cylinder journaled in said casing, ball-bearings between the bottom of said cylinder and the bottom of said casing, a lead-supporting rod passing through central perforations in the bottom of said casing and cylinder, and provided with a spiral, spring connection between said rod and the top of said casing, and rollers journaled on the inner surface of the bottom of said cylinder and contacting with said spiral, whereby longitudinal movement of the rod produces rotary movement of the spiral, substantially as and for the purpose set forth.

5. In a spring-balance scale, a suitably-supported non-rotatable casing provided with a vertical slot, a price-index on a margin of said slot, a vertical computing-cylinder journaled in said casing, a lead-supporting rod extending within said cylinder, a spring lead-hanger D provided with a non-rotatable top cross-piece having a threaded stem C equipped with nuts and provided also with means for preventing rotation, said hanger D having spring connection with said rod, and connections between rod and cylinder, whereby the rod is moving longitudinally turns the cylinder, substantially as and for the purpose set forth.

6. In a spring-balance, the combination of a non-rotating frame providing an external casing and having means for supporting it from above, weighing-springs secured at their upper ends to rigid parts of said frame, a vertically-movable runner which is suspended from the lower ends of said springs and is provided with depending means to support the load, a short-drum rotatably mounted within said casing on a vertical axis and having external horizontal rows of value-indicating figures computed at different rates, said casing having a sight-opening through which portions of said value-indicating rows may be seen, and corresponding value-indicating figures on the outer face of said frame adjacent to the value-indicating rows on the short-drum, and mechanism for translating the vertical movement of the runner into the rotary movements of the short-drum.

7. In a spring-balance, the combination of an external non-rotating frame adapted to be supported from above, weighing-springs secured at their upper ends to rigid parts of said frame, a vertically-movable runner which is suspended from the lower ends of said springs and is provided at its lower end with means to support the load beneath it, a short-drum rotatably mounted within said frame on a vertical axis and having external horizontal rows of value-indicating figures computed at different rates, said external frame being apertured whereby portions of said value-indicating rows may be seen, and corresponding value-indicating figures on the outer face of said frame adjacent to the value-indicating rows on the short-drum, and mechanism for translating the vertical movements of the runner into the rotary movements of the short-drum, substantially as specified.

8. In a spring-balance, the combination of an external non-rotating frame, weighing-springs supported from said frame, a vertically-movable runner which is suspended from said springs and is provided at its lower end with means to support the load beneath it, a short-drum rotatably mounted within said frame on a vertical axis and having external horizontal rows of value-indicating figures computed at different rates, said external frame being provided with a vertical aperture, whereby portions of said value-indicating rows may be seen, and corresponding value-indicating figures on the outer surface of said frame adjacent to said aperture and corresponding with said value-indicating rows on the short-drum, and mechanism for translating the vertical movements of the runner into the rotary movement of the short-drum.

9. In a spring-balance computing-scale, the combination of a suitably-supported vertical non-rotatable casing provided with a price-index, a vertical rotatable computing-cylinder journaled in said casing and provided with circumferential rows of cost computations, a central vertical spiral-equipped motor-transmitting rod, a spring supported from the casing, a motor-transmitting friction member engaging said spiral, one of said motor-transmitting devices being supported by said spring to move vertically and the other connected with said cylinder to transmit rotary motion to said cylinder, and a lead-pan supported from said spring-supported motor-transmitting member, substantially as and for the purpose set forth.

10. In a price-scale, the combination of an outer cylinder having an opening in one face thereof, a second cylinder rotatably mounted in said first cylinder, notations upon one of said cylinders to indicate the weight of an article and its total price and correlated notations on the other cylinder to indicate the price per unit of weight, a rod for suspending the article being weighed fixed against rotation, and a cover connection intermediate said rod and the rotatable cylinder.

11. In a price-scale, the combination of an outer cylinder having an opening in one face thereof, a second cylinder rotatably mounted in said first cylinder, notations upon one of said cylinders to indicate the weight of an article and its total price and correlated notations on the other cylinder to indicate the price per unit of weight, a rod for suspending the article being weighed fixed against rotation, said rod being provided with a cover-thread throughout a portion of its length, and rollers carried by the rotatable cylinder and bearing directly upon said cover-threaded portion of the rod.

700,920. COMPUTING-SCALE. ARTHUR B. HAYDEN, Chicago, Ill., assignor to Computing Scale Company of America, a Corporation of New Jersey. Filed Apr. 9, 1901. Serial No. 64,067. (No model.)

Claim.—1. In a spring-balance computing-scale, a vertically-disposed computing-cylinder, in combination with a cylinder-actuating rod provided with a spiral, a rod-actuating vertically-movable non-rotatable cross-head engaging said spiral, and a lead-support beneath and suspended from said cross-head, substantially as described.

2. In a spring-balance computing-scale, the combination of a suitably-supported vertical non-rotatable casing provided with a price-index, a vertically-disposed rotatable computing-cylinder in said casing, the casing being provided with cost computations, a cylinder-actuating rod journaled in said casing and provided with a spiral, a spring-support, a spring-actuated cross-head, a lead-support connected with said spring and a vertically-movable non-rotatable cross-head disposed vertically above and moving with said lead-support and serving to actuate said rod, substantially as described.

3. In a spring-balance computing-scale, the combination of a suitably-supported vertical non-rotatable casing provided with a price-index,

a vertical rotatable computing-cylinder in said casing provided with cost computations, a vertically-disposed cylinder-actuating rod supporting said cylinder and journaled in said casing, said rod being provided with a spiral, a spring-support standard within said cylinder and supported from the bottom of said casing, a spring supported thereby, a vertically-movable cross-head supported from said spring and having engagement with the spiral of said rod for imparting rotary movement to said rod, and a spring-supported lead-pan, substantially as described.

4. The combination of a suitable frame or casing provided with a price-index, a vertically-disposed computing-cylinder provided with cost computations, a spiral-equipped cylinder-actuating rod supporting said cylinder and having adjustable bearings at the ends of said casing, a spring-support standard within said cylinder and supported from said casing, a spring supported thereon, a vertically-movable cross-head engaging the spiral of said rod and serving to rotate the rod, and a spring-supported lead-receiving pan or platform, substantially as described.

5. In a spring-balance computing-scale, a suitable casing, a computing-cylinder, a spring-support standard of adjustable height supported within said casing, a spiral-equipped cylinder-actuating rod supporting said cylinder and journaled in said casing, a spring connected with said standard, a vertically-movable cross-head engaging the spiral of said rod and serving to rotate said rod, and a spring-supported lead-receiver vertically beneath and actuating said cross-head, as described.

6. In a spring-balance computing-scale, the combination of a suitably-journaled vertically-disposed spiral-equipped cylinder-actuating rod, a computing-cylinder fixed to rotate therewith, a spring-support, a vertically-movable cross-head within said cylinder and having engagement with the spiral of said rod and serving to rotate said rod, and a spring-supported lead-receiver moving with said cross-head, substantially as described.

7. In a computing-scale, the combination of a suitably-journaled vertically-disposed spiral-equipped cylinder-actuating rod, a computing-cylinder fixed to rotate therewith, a spring-support, a spring, a vertically-movable cross-head, a friction-bearing between said cross-head and spiral of said rod, and a spring-supported lead-receiver vertically beneath and actuating said cross-head, substantially as described.

8. In a spring-balance computing-scale, the combination of a suitably-journaled vertically-disposed spiral-equipped cylinder-actuating rod, a computing-cylinder fixed to rotate therewith, a spring-support, a spring, a vertically-movable cross-head provided with spiral-engaging means, a spring-supported lead-receiver, and a vertical guide for said cross-head, substantially as described.

9. In a scale, the combination of a casing, a spring-support standard supported from the lower end of said casing, a computing-cylinder including said standard, a spiral-equipped rod fixed to rotate with said cylinder, a spring, a vertically-movable cross-head engaging the spiral of said rod, a guide for said cross-head, a friction-bearing between said cross-head and guide and a spring-supported lead-receiver, substantially as described.

700,921. SHOWERING. HENRY T. HANCOCK, Los Angeles, Cal.
Filed Dec. 4, 1901. Serial No. 64,576. (No model.)

Claim.—1. The combination with a pair of shoulder-straps secured together at their rear ends, and having attached thereto a snap-hook; a cut-off ring adapted to engage said hook, having curved flange and engaging eyes; back tabs, having button-loops at their lower ends for engaging the back buttons, and having cord-engaging eyes on their upper ends; and an equalizing-rod, having button-loops for engaging the side buttons; the said cord passing from the side buttons up to and through the eyes on the cut-off ring, then down to and through the eyes on the back button-tabs, then up into a fastening on the cut-off ring; the said cord adapted to render freely through said eyes.

2. A pair of suspenders provided at their rear with a hook, a cut-off ring or loop, eye-tapes connected with the ring or loop, an equalizing-rod adapted to render freely through the eye-tapes, rear tabs provided at their lower ends with button-loops to button to the rear trousers-buttons and having at their upper ends eye-tapes adapted to receive the

equalizing-cord and to permit the same to run freely throughout, the equalizing-cord having button-loops for securing it to the side bottom.

3. The combination of the shoulder-strap, loop (I) connected thereto, cast-off ring or loop (F) detachably connected thereto, said cast-off ring or loop having eyelets thereon, equalizing-cord passed loosely through said eyelets, and button-loops (C, C', attached to the cord and loops D', D', loosely connected with the cord.

700,922. APPARATUS FOR APPLYING HOLDING-CLASPS TO BARRICADES. FRANKLIN B. HANCOCK, Louisville, Ky., assignor of two-thirds to CURTIS PAPA and ALFRED THURMAN PAPA, Louisville, Ky. Filed Aug. 28, 1901. Serial No. 73,000. (No model.)

Claim.—1. A clamp for the purpose described consisting of the main frame having side bars and the sliding frame within said bars guided by tongue-and-groove connection thereto, a pressure-bar and rollers on the sliding frame, the rollers being replaceable and serving as a fulcrum, a bracket on the main frame serving as a bearing-fulcrum, and means by which the sliding frame is moved lengthwise within the main frame, all combined.

2. In a clamp for the purpose described, the main frame having a pendant bracket provided with movable retaining-points, the sliding frame within the main frame and having a pressure-bar, a removable roller on this pressure-bar, and a lever having rack-and-pinion connection by which the sliding frame is moved within the main frame, all combined substantially as described.

3. In a clamp as described, the combination of the open-centered main frame, the open-centered sliding frame within the same, the pendant bracket on the main frame and a corresponding bar on the sliding frame, and a cap on the sliding frame substantially above the pressure-bar of the sliding frame, by which cap the upward projecting of the clasp may be prevented or overcome.

4. In a clamp as described, the combination of the outer frame and its supporting-handle, the lever connecting the side bars of said frame and provided with legs, the sliding frame, and means for causing the sliding frame within the main frame, substantially as described.

700,923. ROAD GRADER, GRAPHER, AND WRECKER. CHRISTOPHER HANCOCK, Houston, Tex. Filed Nov. 15, 1901. Serial No. 62,000. (No model.)

Claim.—1. A machine of the class described, comprising a front axle and supporting-wheels thereon, beams having standards adapted for the attachment of an earth-operating blade thereon, said beams having their front ends slidably and pivotally connected to said axle, a cross-bar to which said beams are slidably connected, a frame attached to said front axle, a supporting element for the rear end of said frame, a crank-shaft having its bearings on said frame, a lever to turn said crank-shaft, and a link connecting a crank of said shaft to said cross-bar, substantially as described.

2. In a machine of the class described, a frame comprising a pair of side bars having their front portions diverged forwardly and arched, a cross-bar connecting said arched front portions of said side bars, and a centrally-disposed longitudinal bar, having its front portion arched and connected to said cross-bar, the rear portion of said last-mentioned bar being disposed and secured between the rearwardly-extending portions of said side bars, substantially as described.

3. In a machine of the class described, a frame having forwardly-diverging side bars with arched front portions, a bearing secured between the rear ends of said side bars, a fork-frame, having a vertical spindle journaled in said bearing, a tail-wheel carried by said fork-frame, an axle to which the front ends of said side bars are connected, supporting-wheels on said axle, beams having standards adapted for the attachment of an earth-operating blade thereon, said beams being pivotally connected at their front ends to said axle, a bar connecting said beams together, a crank-

shaft journaled in bearings on said side bars, said crank-shaft having an operating-lever and cranks, and links connected to said bar and adjustably connected to said cranks, substantially as described.

700,924. TRACK-LAYING DEVICE FOR LOCOMOTIVES. DEAN HART HANCOCK, Austin, Tex. Filed June 20, 1901. Serial No. 65,001. (No model.)

Claim.—1. In a track-laying device, the combination with a road-bed, of a road-pipe projecting into the road-bed and having its inner end within the bed formed on a line or level, and means for forcing sand from the bed and through said pipe; substantially as described.

2. In a locomotive track-laying device, the combination with a road-bed, of road-pipes projecting into the road-bed and having their extreme inner ends on a line or level and ejecting devices arranged in said pipes intermediate of their length; substantially as described.

3. In a locomotive track-laying device the combination with the road-bed, of road-pipes projecting into the road-bed and having their extreme inner ends on a line or level with the point overhanging the opening of each pipe and ejecting devices arranged in said pipes intermediate of their length; substantially as described.

4. In a locomotive track-laying device, the combination with the

road-bed, of road-pipes communicating with the road-bed, hand-operated valves controlling the upper ends of said pipes, supplemental pipes communicating with the road-pipes below said valves and with the road-bed and ejecting devices arranged in said road-pipes at a point below their communication with said supplemental pipes; substantially as described.

5. In a locomotive track-laying device the combination with the road-bed, of road-pipes communicating with the road-bed, hand-operated valves controlling the upper ends of said pipes and provided with diaphragm passages, supplemental pipes communicating with the road-bed and with the road-pipes, and ejecting devices arranged in said road-pipes at a point below their communication with said supplemental pipes; substantially as described.

6. In a locomotive track-laying device the combination with the road-bed, of road-pipes communicating with the road-bed, hand-operated valves controlling the upper ends of said pipes, supplemental pipes projecting into the road-bed with their extreme inner ends beveled or on a line and communicating with the road-pipes, and ejecting devices arranged in said road-pipes at a point below their communication with said supplemental pipes; substantially as described.

7. In a locomotive track-laying device, the combination with the road-bed, of road-pipes communicating with the road-bed, hand-operated valves controlling the upper ends of said pipes and provided with diaphragm passages which are open when such valves are closed, supplemental pipes projecting into the road-bed with their extreme inner ends beveled or on a line and communicating with the road-pipes, and ejecting devices arranged in said road-pipes at a point below their communication with said supplemental pipes; substantially as described.

700,925. APPARATUS FOR RINSING BOTTLES. GUSTAVE KEMMEL, Paris, France. Filed Dec. 15, 1901. Serial No. 55,100. (No model.)

Claim.—1. An apparatus for rinsing bottles, comprising a rotary frame rotatable around a vertical shaft and comprising several compartments arranged at equal angles to receive the bottles, a series of bottle-brushes fitted up at a fixed point or station below the path of the bottles, a series of dirt-jets fitted up at a fixed point or station also below the path of the bottles, means to cause the rotary frame to revolve and to bring the compartments of the same to a stop above the said point where the said brushes and the said dirt-jets are stationed, and means to cause the bottles to move downward and upward around the said brushes and the said jets.

2. An apparatus for rinsing bottles, comprising a rotary frame provided with independently-movable beds supporting through the medium of springs framings to receive pigmy-hole-cams for the bottles and plates provided with apertures for holding the bottles, means to cause the said rotary frame to revolve intermittently by connecting the same with and disconnecting the same from a central driving-wheel, means for causing the beds to move downward and upward in their turn together with the said framings, cams, and plates, and series of vertical bottle-brushes and tubes ejecting water under pressure arranged at fixed points so that the bottles will move down into the said brushes and the said tubes.

3. In an apparatus for rinsing bottles having a rotary frame rotatable around a vertical shaft, the combination of a bed vertically movable in the said frame and serving to hold the bottles, of a crank-plate mounted on a rod vertically movable in the frame and resting on a circular path, of a pinion connecting the said bed with the crank-plate, of a bevel-pinion meshing with the said crank-plate, of the circular path in which the pinion meshes when the said rod rests in a means of the circular path.

4. In an apparatus for rinsing bottles having a rotary frame rotatable around a vertical shaft, the combination of vertical rods mounted in

the said frame, of slides movable on the said rods and provided with opening-pins, of a central driving-wheel, of springs to bring the said slides into movement with the said driving-wheel to cause the said rotary frame to revolve, of fixed cams and of collating cams arranged at fixed points to act on the said slides as to put them out of gear with the driving-wheel, of fixed buffer parts arresting the rotary motion of the slides when the latter are displaced by the said cams, and of means of causing the collating cams to rack in order to allow of the corresponding slides again coming into gear with the driving-wheel.

5. In an apparatus for rinsing bottles having a rotary frame rotatable around a vertical shaft, the combination of a bed vertically movable in the said frame, supporting through the medium of springs a framing to receive the bottle-cams and a plate provided with apertures for holding the bottles, of a series of spring-buffers carried by the bed above the bottles, of a crank-and-gear mechanism to cause the said buffers to revolve together with the bottles, and of a fixed beveled rack fixed to the said rotary frame and meshing with one of the wheels of the said gear to operate the said mechanism when the bed moves upward and downward.

700,926. VEHICLE. DEAN C. HANCOCK, Chicago, Ill. Filed Nov. 15, 1901. Serial No. 73,001. (No model.)

Claim.—1. In a vehicle, a frame supported laterally by one or more wheels on each side of said frame operatively connected thereto to have an independent rotating movement in planes at right angles to the planes of their revolution, and a steering-wheel independently mounted and operatively connected with said frame for steering the same, to permit vertical as well as lateral movement of said steering-wheel independently of said frame.

2. In a vehicle, a frame supported laterally by one or more wheels on each side of said frame operatively connected thereto to have an independent rotating movement in planes at right angles to the planes of their revolution, a steering-wheel independently mounted and operatively connected with said frame, and a driving-wheel independently mounted and operatively connected with said frame for driving the same and to permit vertical movement of said driving-wheel independently of said frame.

3. In a vehicle, a frame supported laterally by one or more wheels on each side of said frame operatively connected thereto to have an independent rotating movement in planes at right angles to the planes of their revolution, a steering-wheel independently mounted and operatively connected with said frame to permit vertical as well as lateral movement of said steering-wheel independently of said frame, a driving-wheel independently mounted and operatively connected with said frame for driving the same and to permit vertical movement of said driving-wheel independently of said frame, and a vehicle-body, in combination with supports for said body, whereby said body is supported by said frame and wheels and a reciprocating movement is permitted in the vertical movement of the supporting parts and the vertical movement of said supporting parts is divided between the said parts, and transmission of such motion to the body of said vehicle is diminished.

4. In a vehicle, a frame supported laterally by one or more wheels on each side of said frame operatively connected thereto to have an independent rotating movement in planes at right angles to the planes of their revolution, in combination with a supporting frame independently supported upon wheels for steering and for guiding the same, said frame operatively connected to permit independent vertical movement between said frames.

5. In a vehicle, a frame supported laterally by one or more wheels on each side of said frame operatively connected thereto to have an independent rotating movement in planes at right angles to the planes of their revolution, in combination with a supporting frame independently supported upon wheels for steering and for driving the same, flexible connections operatively connecting said frame to permit independent vertical movement between said frame, a vehicle-body, in combination with means for supporting said body, whereby the weight and support of said body is divided between said supporting parts and vertical movement and vibration of said supporting parts is divided and communicated between said parts and only partially transmitted to the body of said vehicle.

6. In a vehicle, a frame supported laterally by one or more wheels on each side of said frame operatively connected thereto to have an independent rotating movement in planes at right angles to the planes of their revolution, in combination with a supporting frame independently sup-

ported on wheels for steering and for driving the same, flexible connections operatively connecting said frames to permit independent vertical movement between said frames, a vehicle-body for said vehicle, means for supporting said body operatively connected with said frames, whereby the weight and support of said body are divided between and supported by said frames, and mechanism for driving said vehicle mounted upon one of said frames, whereby means for the support and application of the motor is provided independently of the other of said frames, and vibrations from said motor are not transmitted directly to the body of said vehicle.

7. In a vehicle of the class described, the combination of a frame portion carrying two wheels at each side thereof, a front steering-wheel pivotally secured to the frame portion so as to have a vertical as well as a lateral movement arranged at or near the longitudinal center of the vehicle, and a rear driving-wheel pivotally secured to the frame portion so as to have an independent vertical movement and arranged at or near the center of the vehicle, substantially as set forth.

8. In a vehicle of the class described, the combination of a main frame portion provided with two wheels at each side thereof independently pivotally secured thereto so as to have independent lateral movements, a supplementary frame portion carrying a front steering-wheel, and a rear driving-wheel arranged in the longitudinal center of the vehicle and pivotally secured to the main frame so as to permit each wheel to have independent vertical movements, substantially as described.

9. In a vehicle of the class described, the combination of a main frame portion provided with two wheels at each side thereof, means for pivotally securing each wheel to the main frame so as to permit them to have independent lateral movements, a supplementary frame portion arranged along the longitudinal center of the vehicle and provided with a front steering-wheel and a rear driving-wheel, connecting-rod mechanism pivotally connecting the front portion of the supplementary frame to the front portion of the main frame, and connecting-rod mechanism pivotally securing the rear portion of the supplementary frame to the rear portion of the main frame, substantially as described.

700,927. AIR-COMPRESSOR. HARRISON HILL, South Norwalk, Conn. Filed Aug. 17, 1901. Serial No. 73,348. (No model.)

Claim.—1. A compound air-compressor having cylinders, pistons, inlet and discharge valves and cylinder-interduct, means for opening a valve of the second cylinder, and a passage or connecting said interduct with the valve-opening means that the pressure in the cylinder-interduct controls the operation of the valve-opening means, substantially as specified.

2. A compound air-compressor having cylinders, pistons, inlet and discharge valves and cylinder-interduct, means tending to open an inlet-

valve of the second cylinder, a passage or connecting said interduct with the chamber of said inlet-valve that the normal pressure in the cylinder-interduct is exerted oppositely to said holds in check the means tending to open said inlet-valve, substantially as specified.

3. In a compound air-compressor having cylinders, pistons, inlet and discharge valves and cylinder-interduct, a valve-piston, means for moving the valve-piston so it will open a valve of the second cylinder, and a passage or connecting said interduct with the valve-piston chamber that the normal pressure in the cylinder-interduct is exerted oppositely to and holds the means for moving the valve-piston, substantially as specified.

4. A compound air-compressor having cylinders, pistons, inlet and discharge valves and cylinder-interduct, a valve-piston, a spring for moving the valve-piston so it will open a valve of the second cylinder, and a passage or connecting said interduct with the valve-piston chamber that the normal pressure in the cylinder-interduct is exerted oppositely to and holds the means for moving the valve-piston, substantially as specified.

5. A compound air-compressor having cylinders, pistons, inlet and discharge valves and cylinder-interduct, a valve-piston, a spring for moving the valve-piston into contact with a portion of a valve of the second cylinder, and a passage or connecting said interduct with the valve-piston chamber that the normal pressure in the cylinder-interduct is exerted oppositely to and overcomes the spring, substantially as specified.

700,928. TRAIN-ORDER BOX. ISA C. HARRIS, Los Angeles, Cal. Filed Mar. 12, 1902. Serial No. 58,928. (No model.)

Claim.—1. In a gravity-operated semaphore having an operating-cord secured thereto, a sliding order-box to receive a stylus and order-blank, a hook below the same to engage an operating-cord, the cord adapted when hooked thereon to push in front of the box and prevent the box from being opened, a pivoted lock hinged to said box and adapted to close the end of the box when the box is in its closed position, and when the box is drawn out to assume a vertical position leaving the end of the box open and displaying a danger-indicating portion over the open end thereof.

2. A sliding train-order box to receive and hold train-orders in combination with means to operate a semaphore-arm comprising a cord secured at one end thereto and the other end adapted to be hooked onto a hook disposed below the order-box and when hooked to prevent the box being opened; a hook below the order-box; a pivoted lock on said box carrying at one end a closure for said box and a danger-indicating portion at the other end, the said lock adapted to cover the end of the box when the box is slid in and when the box is drawn out to remove the cover from the end of the box and to display the danger portion.

3. A sliding train-order box having a pivoted lock secured thereto, the said lock being provided at one end with a danger-display portion and at the other end with a closure for the box, the said lock being adapted when the box is pushed into the closed position to close the end of the box and to remove the danger-display portion from sight and when the box is drawn out to assume a vertical position in which the closure is removed from the end of the box, leaving it open, and the danger-display portion is displayed over the end of the box.

4. In a gravity-operated semaphore system for railways, a sliding train-order box, a hook below the end of the box, a semaphore-operating cord, secured at one end of the semaphore-arm and the other end adapted to be hooked to the hook, the hook so disposed below the end of the box

that the operating-cord will pass down in front of the bar and prevent the bar from being opened when the cord is locked, whereby the bar cannot be opened for use until the operating-cord is loose permitting the compartment to go to the danger position.

700,828. BED-BOTTOM. JOHN HOLT, San Francisco, Cal. Filed Apr. 4, 1901. Serial No. 54,570. (No model.)

Claim.—1. The combination in a bed-bottom of a frame consisting of end bars extending over the side rails of the bedstead, supporting-blocks resting upon the bedstead-rails having the outer ends flush with those of the end bars, side bars bolted through the inner ends of the blocks and the end bars and suspended therefrom interior to the bedstead-rails, a woven-wire fabric stretched longitudinally over the end bars and connected with the side bars, said fabric having its edges flush with the end bars and overhanging the bedstead-rails, strengthening devices consisting of elastic cables extending in pairs between the ends of the frame, links by which the members of each of said pairs are drawn toward each other, said pairs being so disposed that adjacent members of each pair overlap each other and cross to form supplemental supports intermediate between the center and the ends.

2. The combination in a bed-bottom of a frame, the end bars of which extend and are supported above the bedstead-rails by blocks interposed and resting upon said rails, side bars of said frame bolted through the inner ends of the blocks to the end bars and supported therefrom out of contact with the bedstead-rails, a woven-wire mattress stretched over the end bars having its edges projecting flush with the end bars and over the bedstead-rails, elastic cables stretched between the end bars in contact with the lower surface of the mattress, links by which the central portions of each of the pairs of cables are drawn toward each other whereby the adjacent members of each pair overlap in the form of elongated diamond shapes, and other links extending across the shorter diagonals of the overlapping members and approximately in line with the links by which the tension of each pair is maintained.

700,830. COMPOUND ENGINE. WILLIAM HOPKINS, Dubuque, Iowa; James Hopkins, successor of said William Hopkins, deceased, assignor to the Iowa Iron Works Co., Dubuque, Iowa, a Corporation of Iowa. Filed Oct. 12, 1901. Serial No. 72,593. (No model.)

Claim.—1. In a compound engine, a high and low pressure cylinder placed one above the other, two sets of valves seated on opposite sides of the cylinders, each set connected to a common stem, and means connected with the stems of the valves for operating said valves, for the purposes shown.

2. In a compound engine, two cylinders placed one above the other, a passage for the exhaust-steam from the high-pressure cylinder between the two cylinders, two sets of puppet-valves upon each side of the cylinders, each set connected to a common stem, and means, connected with said stems, for operating said valves, for the purposes shown.

3. In a compound engine, two cylinders the one a high-pressure and the other a low-pressure placed one above the other, a passage-way for the exhaust-steam from the high-pressure cylinder between the two cylinders, a set of valves connected to a common stem for introducing the fresh steam to the forward end of the high-pressure cylinder and the exhaust-steam into the forward end of the low-pressure cylinder, a set of

valves connected to a common stem on the opposite side of the rear of the cylinder for receiving the exhaust-steam from the high-pressure cylinder and transmitting it into said passage-way and also for receiving the steam from the low-pressure cylinder and discharging it, for the purposes shown.

4. In a compound engine two cylinders one a high-pressure and the other a low-pressure placed one above the other, a passage-way for the exhaust-steam between the two cylinders, a set of valves connected to a common stem for introducing the fresh steam into the rear end of the high-pressure cylinder and the exhaust-steam into the rear end of the low-pressure cylinder, and a set of valves connected to a common stem placed upon the opposite side near the forward end of the cylinder one for receiving the exhaust-steam from the high-pressure cylinder and transmitting it to the passage-way, the other for receiving the exhaust from the low-pressure and discharging it into the air, and means connected with the valve-stems for operating the same, for the purposes shown.

5. In a compound engine, a high and low pressure cylinder placed one above the other, a passage-way between the cylinders, two sets of puppet-valves, each set united to a common stem and seated upon one side of the cylinder for introducing the fresh and exhaust steam from both ends of the cylinders, two sets of puppet-valves each set connected to a common stem for receiving and discharging the exhaust from the cylinders and means connected with the valve-stems for operating the same, whereby the four upper valves receive the fresh steam and introduce it into the high-pressure cylinder and discharge the exhaust-steam into the passage-way from the high-pressure cylinder, and the four lower valves operate the piston in the low-pressure cylinder and discharge the exhaust-steam into the air.

6. In a compound engine a high and low pressure cylinder one above the other, a passage-way between the said cylinders and eight puppet-valves each consisting of a casing, shoulder within the casing, a ball, a hollow circular valve and double valve-seat, two of said valves forming a set and each set connected to a common stem, and means connected with the stems for operating the said valves for the purposes shown.

7. A compound engine, consisting of two cylinders placed one above the other, a passage-way between the cylinders, two puppet-valves connected to a common stem and seated upon one side of the cylinder near the forward end, another set consisting of two valves and united to a common stem and seated upon the same side of the cylinder near the rear, two other sets of valves each set consisting of two valves united to a common stem, seated upon the opposite side of the cylinders and means connected with the stems of the valves for operating the same, whereby the four sets of valves operating the eight valves are operated by the valve-gear necessary for operating a single high-pressure cylinder.

700,981. VOTING-MACHINE. GEORGE L. BARK, Adrian, Mich., assignor of two-thirds to David H. Bark, Adrian, Mich. Filed Mar. 28, 1901. Serial No. 55,504. (No model.)

Claim.—1. In a voting-machine, the combination with a suitable frame, of a series of counters mounted therein, movable buttons adapted to rotate said counters, a channelled bar movable transversely of the frame,

an aligning-bar mounted upon said transversely-movable channelled bar and movable thereon, said aligning-bar engaging the channels of said movable bar, adapted to engage said movable buttons and carrying them simultaneously into alignment vertically of the frame.

2. In a voting-machine, the combination of a suitable frame having on its face spaces adapted to contain the names of candidates and a set of counting-gears for each candidate a series of horizontal channels dividing said spaces, a vertical channel communicating with and common to all of said horizontal channels, a series of movable buttons adapted to lie in said horizontal channels and to be moved from one horizontal channel to another through said vertical channel, said buttons being adapted to be carried from the horizontal channels into the vertical channel and means for restoring said buttons from the vertical channel into their respective horizontal channels.

3. In a voting-machine, the combination of a suitable frame, a series of registering-gears in the frame adapted to register the votes of candidates, a series of horizontal channels in the frame adjacent to said registering-gears, a series of buttons movable in said channels and adapted to actuate said gears, a vertical channel communicating with said horizontal channels, the buttons in said horizontal channels adapted to pass therefrom into said vertical channel and lie therein in a vertical row, a movable agent adapted to engage the buttons in the vertical channels and carry them upward into said horizontal channels and means for moving said agent.

4. In a voting-machine, the combination of a suitable frame, a series of registering-gears in said frame, a series of horizontal channels in the frame adjacent to said registering-gears, a vertical channel common to and communicating with all of said horizontal channels, a series of buttons movable in said horizontal channels and adapted to actuate said registering-gears, means for carrying the buttons from the horizontal channels into said vertical channel and means for restoring the buttons from said vertical channel into said horizontal channels.

5. In a voting-machine, the combination of a frame, a series of counting-gears in said frame, a series of horizontal channels adjacent to said counting-gears, a series of buttons movable in said channels and adapted to actuate said counting-gears, a vertical channel communicating with said horizontal channels whereby said horizontal channels are made to communicate through said vertical channel, a movable plate adapted to engage the buttons in said horizontal channels to carry them into said vertical channels, means for actuating said plate and means for disengaging the buttons from said vertical channel into said horizontal channels.

6. In a voting-machine, the combination of a suitable frame, a series of counting-gears in said frame, a series of horizontal channels in the frame adjacent to said counting-gears, a series of buttons movable in said channels adapted to actuate said gears, a vertical channel communicating with said horizontal channels, a series of spring-actuated plungers adapted to extend into said vertical channel in line with said horizontal channels, means for carrying the buttons upwardly in said vertical channel where-

by they are engaged by said plungers and directed into said horizontal channels.

7. In a voting-machine, the combination of a suitable frame, a series of movable registering-gears therein, a series of horizontal channels adjacent to said registering-gears, buttons movable in said channels adapted to place said registering-gears in a voting position, means for actuating the registering-gears when in a voting position, a movable tripping-frame connected with said gear-actuating means, a vertical channel communicating with said horizontal channels and adapted to contain the movable buttons in vertical alignment, a transversely-movable plate standing adjacent to said vertical channel contiguous to the buttons when lying therein and means connecting said plate with the movable tripping-frame.

8. In a voting-machine, the combination of a suitable frame, counting-gears in said frame, a slot adjacent to said counting-gears, a button movable in said slot adapted to engage said gears and carry them into engagement with an actuating voting-frame, said voting-frame being movable vertically, a pivoted dog adapted to engage said frame to raise it, a series of levers attached to said dog, a sliding bar carrying a rod adapted to engage said button and a projection on said bar adapted to engage one of the series of levers connected with said dog.

9. In a voting-machine, the combination with a suitable frame, of a series of registering-gears, a series of horizontal channels adjacent to said gears, buttons movable in said channels adapted to engage and actuate said gears, a vertical channel communicating with said horizontal channels adapted to contain said buttons in vertical alignment, a series of spring-actuated plungers extending into said vertical channel in line with said horizontal channels, a vertically-movable bar having inclined shoulders engaging said plungers, an arm pivoted to said vertically-movable bar, a horizontally-movable bar having a stop adapted to engage the free end of said arm to raise said vertically-movable bar, and a rod attached to said horizontally-movable bar adapted to engage said buttons.

10. In a voting-machine, the combination of a suitable frame having a series of horizontal slots in its face, a series of registering-gears adjacent to said slots, buttons movable in said slots adapted to actuate said gears, a vertical channel communicating with said horizontal slots adapted to receive the buttons from said slots, a horizontally-movable bar carrying a vertical rod adapted to engage said buttons, a gravity-pawl for locking said bar when drawn outwardly, a vertically-movable rack having a pin adapted to engage the buttons in said vertical slot, said rack having a second pin at its upper end adapted to engage said pawl and disengage it from said bar when said rack is down, and means for moving said rack vertically.

11. In a voting-machine, the combination of a frame or case, having channels in the face thereof, pins movable in said channels, a slide in the case at the front of said channels adapted to be engaged by a pin, a perforating-finger carried by said slide movable into contact with the inclined shoulder of a vertically-movable rod, a strip of paper adjacent to said perforating-finger and means for actuating said rod to carry the inclined shoulder against said finger and cause a perforation in said paper.

12. In a voting-machine, the combination of a frame, or case, having a horizontal channel therein, a button movable in said channel, a movable slide extending into the path of said-button, said slide carrying a perforating-finger pivoted therein, a strip of movable paper adjacent to said perforating-finger, means for moving said paper connected with said slide, an actuating device adapted to engage said finger when moved into a position to perforate said paper, a second slide adapted to cover an opening exposing said strip of paper and means for moving said second slide from said opening.

13. In a voting-machine, the combination of a case, registers mounted in said case, agents movable in the case adapted to control said registers, a record-strip, a movable slide carrying a perforator adapted to perforate said strip, said slide being adapted to be engaged by one of the movable agents in the case to place the perforator in operative position.

14. In a voting-machine, the combination of a case, registers in said case for recording the votes cast for the candidates on the several tickets, means for actuating said registers, a record-strip upon which may be written the name of a candidate for any office, means for making an indicating-mark by the name of the candidate written by the elector, through the operation of the register-actuating device and means to prevent voting for any other candidate for the same office except the one whose name is written on the record-strip.

700,982. WALL-TIE. CHARLES T. EMMER, Akron, Ohio. Filed Sept. 2, 1901. Serial No. 74,192. (No Model.)

(Main.—1. A wall-tie consisting of a plurality of interlocking wires in the form of a loose braid with the interstices between the wires of sufficient size to permit the entrance therein of cement or similar substance, substantially as shown and described.

2. An improved wall-tie consisting of a number, preferably three

wires, braided into a loose plait, and flattened between rolls, substantially as shown and described.

700,988. BUFFER FOR CUTTER-GUARDS. RICHARD E. LEWIS, Chicago, Ill. Filed Aug. 12, 1901. Serial No. 71,800. (No model.)

Claim.—1. In a machine of the character specified, the combination with a cutter-bar and its guard, of an independent deflexor slidably connected to said guard, a bar located underneath the guard and supporting said deflexor and means for operating said deflexor, substantially as and for the purpose set forth.

2. In a machine of the character specified, the combination with a cutter-bar and its guard, of independent deflexors slidably connected to each of said guards, a bar located underneath the guards and supporting said deflexors, and means for operating said deflexors, substantially as and for the purpose set forth.

3. In a machine of the character specified, the combination with a cutter-bar and a series of guards therefor, of deflexors located adjacent to said guards, said deflexors being provided with spring-hooks, a bar supporting said deflexors and means for operating said deflexors, substantially as and for the purpose set forth.

4. In a machine of the character specified, the combination with a cutter-bar and a series of guards therefor, of deflexors located adjacent to said guards, a bar located underneath the guards and supporting said deflexors, means for adjusting said bar, and means for operating said deflexors, substantially as and for the purpose set forth.

5. In a machine of the character specified, the combination with a cutter-bar, a series of guards for said cutter-bar, and a deflexor-bar located underneath the guards carrying deflexors adjacent to the guards of the cutter-bar, of means comprising foot-treads or connections, for elevating the deflexor-bar, intermediate of said bar and treads, substantially as and for the purpose set forth.

700,984. APPARATUS FOR CONDENSING SMOKE, FUMES, AND GASES. WILLIAM E. JAMES, Denver, Colo., assignor to the Smoke Eliminator and Fume Condenser Company, Pacific, Colo. Filed Feb. 4, 1901. Serial No. 61,681. (No model.)

Claim.—1. In an apparatus for condensing smoke, fumes and gases, the combination of a condensing-tank, means for introducing water in the form of a spray into the tank, a conduit leading from the tank and communicating with the condensing-tank for discharging the products of combustion therefrom, means for introducing a jet of steam into the tank at the discharge extremity of the said conduit, to give the desired velocity, and means mounted on the wall of the tank directly opposite the discharge extremity of said conduit, for temporarily expanding said products in the tank to facilitate condensation, substantially as described.

2. In an apparatus of the class described, the combination of a tank, means located in its upper portion and connected with a supply source, for discharging water thereinto in the form of spray, a conduit leading from the tank and communicating with the tank, its discharge extremity being reduced in size, a steam-pipe entering the smoke-conduit, and arranged to introduce steam into the tank through the discharge extremity of the smoke-conduit, and a receiver mounted in the tank opposite the discharge extremity of the smoke-conduit, to facilitate condensation.

3. The combination of a condensing-tank, means for spraying water downwardly from the upper portion of the tank, a smoke-flue entering the tank below the water-spraying means, means for discharging a steam-jet into the tank through the discharge extremity of the smoke-flue, and an adjustable receiver mounted in the tank opposite the smoke-flue entrance, to facilitate condensation.

4. In a condensing apparatus, the combination of a tank provided with a suitable outlet at its bottom, a perforated pipe located in the upper

extremity for spraying water downwardly thereinto, means for discharging the products of combustion into the tank under pressure, and a funnel-shaped receiver located opposite the discharge for said products to facilitate condensation.

700,985. WINDOW-CASH VENTILATOR. JOHN JACOB, Chicago, Ill. Filed Jan. 15, 1902. Serial No. 80,720. (No model.)

Claim.—1. A window-cash ventilator comprising a tube adapted to extend through an opening in the cash member, and made of a length approximately equal to the width of the cash member, a diaphragm extending across the bore of the tube at the inner end thereof, a damper-plate engaging the diaphragm, a shaft affixed to the damper-plate and having relative engagement with said diaphragm and formed at its inner end to provide an operating knob or handle, said diaphragm and plate being provided with registering apertures which are adapted to be brought into and out of register by rotation of said plate, and a shield or hood projecting outwardly over the outer end of said tube.

2. A window-cash ventilator comprising a tube adapted to extend through an opening in the cash member, and made of a length approximately equal to the width of the cash member, a diaphragm extending across the bore of the tube at the inner end thereof, a relative damper-plate engaging the diaphragm, said diaphragm and plate being provided with registering apertures which are adapted to be brought into and out of register by rotation of said damper-plate and a shield or hood made integral with the upper margin of said tube and extending outwardly therefrom.

3. A window-cash ventilator comprising a tube adapted to extend through an opening in the window-cash, and made of a length approximately equal to the width of the cash member, a diaphragm contained within the tube and extending across the bore thereof, a relative damper-plate engaging the diaphragm, the diaphragm and damper-plate being provided with registering apertures which are adapted to be brought into and out of register by rotation of said damper-plate, and an operating knob or handle connected with said damper-plate and contained entirely within the bore of the tube.

4. The combination with a window-cash provided with a through-opening, of a ventilator comprising a diaphragm which extends across said opening, a movable plate engaging said diaphragm, said plate and diaphragm being provided with apertures which are adapted to be brought into and out of register by movement of said plate, and a contracted funnel-shaped casing located between said diaphragm and the outer end of said opening.

5. The combination with a window-cash provided with a through-opening, of a ventilator comprising a diaphragm which extends across said opening, a movable plate engaging said diaphragm, said plate and diaphragm being provided with apertures which are adapted to be brought into and out of register by movement of said plate, a constricted funnel-shaped casing located between said diaphragm and the outer end of said opening, and a shield or hood projecting from the outer face of said cash over said opening.

700,986. PUMP. ALFRED E. JOHNSON, Victor, Colo. Filed May 20, 1901. Serial No. 61,108. (No model.)

Claim.—1. In a pump, the combination of a cylinder composed of two overlapping parts shaped to form a cavity whose inner portion is curved and communicates with the cylinder-chamber, and whose outer extremity is exposed, a packing-gland adapted to enter said cavity between the cylinder parts, a plunger-stem, a hollow lower plunger connected with said stem, the said plunger being provided at its upper extremity with a valve-seat having openings separated by ribs, a closed upper plunger also connected with the valve-stem, bolts attached to the upper plunger and forming valve-seats independent of the plunger-stem, a valve composed of sections slidable vertically on said stem, the dividing-lines between the valve parts being arranged to coincide with the ribs of the valve-seat, to prevent leakage when the valve is seated, the upper part of the cylinder being provided with an opening to permit access to the mechanism within for the purpose of repair, and a door detachably connected with the cylinder for closing said opening.

2. In a pump, the combination with a cylinder, of upper and lower plungers adapted to move therein, one plunger being closed and the other open, a stem with which the plungers are connected, the lower plunger having a valve-seat at its upper extremity, said seat having ribs separating openings, bolts attached to the upper plunger, a valve located between the plungers, arranged around the plunger-stem, and composed of sections slidable vertically on the bolts which form stems thereof, the divisions between the valve-sections, being arranged to coincide with the ribs between the openings of the valve-seat, the upper portion of the cylinder adjacent the valve, being provided with an opening to permit access to the mechanism within for purposes of repair, and a door detachably connected with the cylinder for closing said opening.

3. In a water-pump of the differential-plunger type, the combination with a cylinder, a plunger-stem, and upper and lower plungers connected with the stem, the lower plunger having a valve-seat at its upper extremity, of guide-stems detachably connected with one of the plungers, a valve composed of sections slidable on said stem and adapted to engage the valve-seat of the lower plunger, the upper portion of the cylinder having an opening to permit access to the mechanism within for purposes of repair, and a door normally closing said opening, the arrangement being such that the plungers are free to turn on their stem, to bring each valve-section and its guide-stem to a position opposite said door or opening in the upper part of the cylinder.

700,987. GRAMOPHONE-BRAKE. ROBERT E. JOHNSON, Philadelphia, Pa. Filed Aug. 8, 1906. Serial No. 51,578. (No model.)

Claim.—1. In a brake for gramophone turn-tables, the combination

with the turn-table, of a pivoted lever secured below the turn-table adjacent the periphery thereof, a friction-heel arranged on the free end of said lever in close proximity to the periphery of the turn-table, a spring connected at one end to the pivoted lever in front of its pivot and at its other end to the casing of the machine on a dead line with its connection with the pivoted lever, substantially as described.

2. In a brake for gramophones and the like, the combination with the turn-table, of a brake-lever pivoted to the frame of the machine below the turn-table, an upturned end formed on the free end of said brake-lever, a laterally-extending arm formed on said end having a friction-heel adapted to contact with the periphery of the turn-table, a spring pivoted to the brake-lever in front of its pivotal point, and having its other end secured to the machine-frame on a dead-center with its point of attachment to the brake-lever whereby on the moving of the brake-lever the spring is brought into action and the friction-heel thrown in frictional contact with the periphery of the turn-table, substantially as described.

3. In a brake for gramophones and the like, the combination with a revolving turn-table, of a lever pivoted to the frame of the machine below the turn-table, a friction-heel arranged on the free end of the lever in a plane with the periphery of the turn-table, a spring secured to said lever in front of its pivot having its other end secured to the machine on a dead-center with its point of attachment to the brake-lever, and means for automatically throwing said brake-lever off of its dead-center at predetermined times for the purpose described.

4. The combination of a revolvable turn-table, a sound-record carried thereby, a record-groove formed in said record, a pivotally-mounted reproducer-support, a reproducer carried thereby, means for shunting the reproducer laterally when the end of the record-groove has been reached, a pivoted brake-lever secured below the turn-table adjacent thereto, a friction-heel arranged on the free end of said lever, a spring adapted to hold the brake-lever in normal position and means connected with the reproducer-support for throwing the brake immediately after the reproduction has been completed, substantially as described.

5. The combination of a revolvable turn-table, a sound-record carried thereby, a record-groove formed in said record, a pivotally-mounted reproducer-arm, a reproducer carried thereby, means for shunting the reproducer laterally when the end of the record-groove has been reached, a pivoted brake-lever secured below the turn-table adjacent thereto, a friction-heel arranged on the free end of said lever, a spring connected at one end to the brake-lever in front of its pivot and at its other end to the casing of the machine on a dead-center with its point of connection with the brake-lever, and mechanism connected with the brake-lever adapted to be operated by the reproducer-arm to throw the brake immediately after the reproduction has been completed, substantially as described.

6. The combination of a revolvable turn-table adapted to support a sound-record, a pivotally-mounted reproducer-arm, a reproducer carried thereby, means for shunting the reproducer laterally when the end of the record has been reached, a pivoted brake-lever secured below the turn-table adjacent thereto, a friction-heel arranged on the free end of said lever, a spring connected at one end to the brake-lever in front of its pivot and at its other end to the casing of the machine on a dead-center with its point of connection with the brake-lever, a lever-arm pivoted to the machine-casing having one end extending beyond the turn-table periphery, a link connection between the lever-arm and the brake-lever, and means carried by the reproducer-arm for tripping the lever-arm and automatically operating the brake to stop the turn-table immediately upon the completion of the reproduction, substantially as described.

7. The combination of a revolvable turn-table adapted to support the record, a pivotally-mounted reproducer, means for shunting the reproducer laterally when the end of the record-groove has been reached, a brake-lever pivoted to the frame of the machine below the turn-table, an upturned arm formed on the free end of said brake-lever having a friction-heel adapted to contact with the periphery of the turn-table, a spring secured to the brake-lever in front of its pivotal point having its other end

connected in the machine-frame on a fixed screw with its point of connection with the brake-lever, a projection, *f*, formed on the brake-lever, an arm, *g*, pivoted intermediate its length to the frame, a link connecting said arm with the leg, *f*, and a depending arm, *h*, carried by the reproducer adapted to engage the free end of the arm, *g*, after the reproduction has been completed, substantially as described.

700,988. BANDAGE. ROBERT W. JOHNSON, New Brunswick, N. J.
Filed Mar. 1, 1902. Serial No. 94,599. (No model.)

Claim.—1. An absorbent bandage consisting of series of layers of rimped cellulose tissue or paper, a thicker layer of absorbent cotton above said rimped paper, another thick layer of non-absorbent cotton under said rimped paper, and a taffia covering including all the layers, substantially as described.

2. An absorbent bandage consisting of series of layers of rimped tissue-paper, a layer of absorbent cotton above said paper, a layer of non-absorbent cotton under said rimped paper, and a covering including all the layers, substantially as described.

700,989. SURGICAL DRESSING. ROBERT W. JOHNSON, New Brunswick, N. J. Filed Mar. 1, 1902. Serial No. 94,599. (No model.)

Claim.—1. A surgical dressing consisting of series of layers of rimped cellulose tissue-paper, and a very thin bat of absorbent cotton between each layer of rimped paper and adhering thereto substantially as described.

2. A surgical absorbent dressing consisting of series of layers of rimped cellulose tissue-paper, and a thin bat of absorbent cotton between each layer of rimped paper in combination with a wrapper of tissue-paper impervious to air substantially as described.

700,940. BANDAGE. ROBERT W. JOHNSON, New Brunswick, N. J.
Filed Mar. 2, 1902. Serial No. 94,601. (No model.)

Claim.—An absorbent bandage consisting of series of layers of rimped cellulose tissue-paper, a very thin bat of absorbent cotton between each layer of rimped paper and adhering thereto, a thicker layer of absorbent cotton above said rimped paper, another thick layer of non-absorbent cotton under said rimped paper and a taffia covering including all the layers substantially as described.

700,941. PROCESS OF TREATING COPPER OR OTHER ORE FOR WITHDRAWING THEREOF METALS. NATHANIEL S. KERN, Arlington, N. J. Filed Mar. 1, 1902. Serial No. 94,595. (No specimens.)

Claim.—1. The process of obtaining a reguline metal from its ore; which consists in powdering the ore; treating the powdered ore; treating the treated ore with a solvent of the metal; and electrolyzing the solution to deposit the metal therefrom, by passing it as an electrolyte, through a succession of two, or more, electrolytic cells, arranged so that

the cells are connected in electrical series with a source of electricity; the anodes insoluble; the electrodes of each cell in electrical multiple; and having gradually-increasing surfaces; whereby there is a gradual reduction of the current density as the metal of the electrolyte is deposited.

2. The process of electrolyzing a solution of a metal, to deposit the metal therefrom; which consists in passing it, as an electrolyte, through a succession of two, or more, electrolytic cells, arranged so that the cells are connected in electrical series with a source of electricity; the anodes insoluble; the electrodes of each cell in electrical multiple; and having gradually-increasing surfaces; whereby there is a gradual reduction of the current density as the metal of the electrolyte is deposited.

700,942. PLAYING-BALL. BRADMAN KIMBALL, Boston, Mass., assignor to The Kimball Manufacturing Company, a Corporation of New Jersey. Filed Apr. 9, 1902. Serial No. 103,289. (No model.)

Claim.—1. A playing-ball comprising a core and a shell thereon; said core consisting of a mass of bits of rubber and being held under compression by said shell.

2. A playing-ball comprising a core and a shell of plastic material thereon; said core consisting of a mass of covered rubber threads or strips held under compression by said shell.

3. A playing-ball comprising a shell and a core; the latter consisting of windings or layers of tensioned rubber threads, and at least a considerable portion of said windings being covered, so that at least a large part of the threads are released and exert a constant expansive pressure upon said shell.

4. A playing-ball comprising a shell of plastic material and a core; the latter consisting of a mass of fragments of rubber threads, whose tendency is to shorten and thicken, said tendency being resisted by said shell.

5. A playing-ball comprising a shell and a core; the latter consisting of a mass of fragments of rubber threads or strips, the ends of said fragments being concealed, and said fragments exerting pressure upon said shell.

6. A playing-ball comprising a shell and a core; the latter consisting of windings or layers of tensioned rubber threads; said core being mutilated at different points, and many or all of the rubber threads being released by reason of said mutilation and tending constantly to expand said shell.

7. A playing-ball comprising a gutta-percha shell and a core; the latter consisting of windings or layers of tensioned rubber threads; said shell and core being mutilated at different points, and the rubber threads being released by reason of said mutilation, and tending constantly to expand said shell.

8. A playing-ball comprising a shell and core; the latter consisting of windings or layers of tensioned rubber threads, and at least a portion of said windings being covered, whereby at least some of the threads are released and exert a constant expansive pressure upon said shell; and the latter having closed apertures.

9. A playing-ball comprising a shell which consists of welded segments of plastic material, and a core; the latter consisting of windings or layers of tensioned rubber threads, and at least a portion of said windings being covered, whereby at least a portion of the threads are released and exert a constant expansive pressure upon said shell.

700,943. BALL-BALL. BRADMAN KIMBALL, Boston, Mass., assignor to The Kimball Manufacturing Company, a Corporation of New Jersey. Filed Apr. 16, 1902. Serial No. 103,290. (No model.)

Claim.—1. A playing-ball comprising a soft-rubber sphere and a shell of plastic material thereon, strips of fabric extending continuously

around said sphere in different directions and being vulcanized thereto and said rubber sphere being held under compression by said fabric strips and shell.

2. A playing-ball comprising a soft-rubber sphere and a shell of celluloid thereon, strips of fabric extending continuously around said sphere in different directions and being vulcanized thereto, said rubber sphere being held under compression by said fabric strips and shell.

3. A playing-ball comprising a soft-rubber sphere and a shell of plastic material thereon, strips of fabric extending continuously around said sphere in different directions and being vulcanized thereto, and said rubber sphere being held under compression by said fabric strips and shell, the threads of said fabric strips extending diagonally of said strips.

700,944. PLAYING-BALL. **BRADEN KIMBALL,** Boston, Mass., assignor to The Kimball Manufacturing Company, a Corporation of New Jersey. Filed Apr. 17, 1902. Serial No. 108,961. (No model.)

Claim.—1. A playing-ball comprising a cloth-covered rubber sphere in a state of expansion upon a solid core of gutta-percha; said cover consisting of hemispherical segments and a strip of fabric vulcanized upon each segment and reinforcing the joint therebetween.

2. A playing-ball comprising a sphere of soft rubber, a cover of fabric vulcanized thereon, and a shell formed of plastic material upon said sphere.

3. A playing-ball comprising a hollow sphere of soft rubber, a layer of fabric vulcanized upon one of its surfaces, and a hard shell formed of plastic material and cemented upon said sphere.

4. A playing-ball comprising a sphere of soft rubber, a layer of fabric vulcanized upon its outer face, and a shell formed of gutta-percha and filled by said sphere.

5. A playing-ball comprising a hollow sphere of soft rubber, hemispheres of fabric vulcanized thereon, a fabric strip closing the joint between said fabric hemispheres and vulcanized thereon, and a shell formed of plastic material holding said sphere under compression.

6. A playing-ball comprising a sphere of soft rubber, a layer of fabric vulcanized thereon, said sphere being distended by molten material injected thereto; and a plastic shell upon said sphere.

7. A playing-ball comprising a sphere of soft rubber, a layer of fabric vulcanized upon its outer face; said sphere being distended by plastic material injected thereto; and a shell of plastic material holding said sphere under compression.

8. A playing-ball comprising a hollow sphere of soft rubber, hemispheres of fabric vulcanized thereon, a fabric strip closing the joint between said fabric hemispheres and vulcanized thereon, said sphere being distended by gutta-percha injected thereto; and a shell of gutta-percha upon said sphere.

9. A playing-ball comprising a sphere of soft rubber, a layer of fabric vulcanized thereon, said sphere being expanded upon a solid core of harder material than said rubber; and a shell formed of gutta-percha upon said sphere.

10. A playing-ball comprising a cloth-covered rubber sphere in a state of expansion upon a solid core of springy material, the rubber being vulcanized to the cloth, and a shell formed of plastic material upon said sphere.

11. A playing-ball comprising a cloth-covered rubber sphere in a state of expansion upon a solid core of gutta-percha, said cover consisting of hemispherical segments, a strip of fabric vulcanized upon each segment and reinforcing the joint therebetween, and a shell formed of gutta-percha and holding said sphere under compression.

700,945. GOLF-BALL. **BRADEN KIMBALL,** Boston, Mass., assignor to The Kimball Manufacturing Company, a Corporation of New Jersey. Filed Apr. 21, 1902. Serial No. 108,962. (No model.)

Claim.—1. A playing-ball comprising a substantial shell which consists of windings of celluloid cord, said cord consisting of celluloid having a core of twine, and being wound continuously in different directions and compressed together.

2. A playing-ball comprising a filling and a shell thereon; said shell consisting of windings of cord, and said cord consisting of plastic material having a core of twine and being wound continuously in different directions and welded and packed together.

3. A playing-ball comprising a core and a continuous shell holding said core under compression; said shell consisting of compressed windings of cord, and said cord consisting of celluloid having a core of twine.

4. A playing-ball comprising a hard center piece, a soft-rubber sphere thereon, and a shell constructed of celluloid cord wound continuously in different directions and compressed; said cord consisting of celluloid having a core of twine.

700,946. FACING FOR GOLF-CLUBS. **BRADEN KIMBALL,** Boston, Mass., assignor to The Kimball Manufacturing Company, a Corporation of New Jersey. Filed Apr. 21, 1902. Serial No. 108,967. (No model.)

Claim.—1. A bevel-edge facing for a club consisting of piles of celluloid incorporated with piles of open-mesh fabric, said facing having the form of a tablet of suitable size to apply directly to the head of a club.

2. A bevel-edge, dovetail facing for a club consisting of piles of celluloid incorporated with fabric, said facing having the form of a tablet of suitable size to apply directly to the head of a club.

3. A dovetail facing for a club consisting of piles of celluloid incorporated with piles of fabric, the celluloid forming a surface over the edges of the facing, said facing having the form of a tablet of suitable size to apply directly to the head of a club.

4. A bevel-edge dovetail facing for a club consisting of piles of celluloid incorporated with piles of fabric, the celluloid forming a surface over the edges of the facing, said facing having the form of a tablet of suitable size to apply directly to the head of a club.

5. A facing for a club consisting of three piles of celluloid incorporated with two alternating piles of open-mesh fabric, said facing having the form of a tablet of suitable size to apply directly to the head of a club.

6. A facing for a golf-club consisting of layers of celluloid and fabric in alternation, said layers being incorporated together, and said facing being provided with one or more peg-holes, and having substantially the same area as the face of the club.

7. A facing for a club having three layers of celluloid and two layers of fabric incorporated therewith, the outer and inner layers consisting of celluloid, and said facing being provided with peg-holes, and having substantially the same area as the face of the club.

8. A dovetail facing for a golf-club consisting of a plurality of piles of celluloid and a plurality of alternating piles of fabric incorporated therewith, said facing being provided with peg-holes, and having substantially the same area as the face of the club.

9. A facing for a golf-club, consisting of a plurality of layers of celluloid, and at least one layer of fabric intervening between said celluloid layers, said facing being provided with peg-holes, and having substantially the same area as the face of the club.

700,947. SHAVING-STICK. BYRON T. KENDRICK, Boston, Mass., assignor to the J. T. Robertson Company, Manchester, Conn., a Corporation. Filed Mar. 5, 1901. Serial No. 49,300. (No model.)

Claim.—1. The improved shaving-stick herein described, consisting of a tubular case open at both ends, a cylindrical piece of soap fitting and movable in said tube, a cylindrical block having a circumferential groove and an annular metallic spring mounted in said groove and having a diameter exceeding that of said case, all combined and operating substantially as shown and for the purpose specified.

2. The improved shaving-stick herein described, consisting of a tubular case open at both ends and having an annular bead near one of its ends, a cylindrical piece of soap fitting and movable in said tube, a cylindrical block having a circumferential groove, an annular metallic spring mounted in said groove and having a diameter exceeding that of said case, and a cap covering the top of said case and in contact with said annular bead, substantially as specified.

700,948. BURIAL DEVER. RICHARD E. KENNY, Caldwell, Mich., assignor to the National Burial Device Company, Caldwell, Mich. Filed Oct. 24, 1900. Serial No. 74,503. (No model.)

Claim.—1. In a burial device, the combination of the lowering bolts or levers; a broad hook A made of sheet metal with a turned-up engaging portion A'; a broad hook B of sheet metal with a downwardly-turned engaging portion B', the metal being folded to form a shield B'' below the engaging-point of the hook B, a greater distance than the length of the engaging portion A' of the hook A, causing as specified.

2. In a burial apparatus, the combination with lowering straps or cords; of a hook having an upwardly-projecting engaging portion on one of said straps or cords; and a hook on the opposite end having a downwardly-projecting portion to support its point in an elevated position to permit the disengagement of the first hook when the tension is slackened.

3. In a burial apparatus, the combination of the lowering straps or cords; of a member having a downwardly-pointing hook portion; an opposite member having a hook adapted to engage said hook portion; and a support to hold the hook portion of said first member in an elevated position when the same is resting on the ground or floor, whereby said hooks will be disengaged when tension is slackened on the straps, for the purpose specified.

700,949. BLENDING-PIN FOR COWS. OTTO S. KLEINWASHER, St. Louis, Mo., assignor of one-half to Gilbert Smith, St. Louis, Mo. Filed Jan. 11, 1900. Serial No. 69,577. (No model.)

Claim.—1. In a pin of the class described, the combination of an outer wall, an inner wall concentric with said outer wall and extending from a greater elevation than the outer wall to provide an overlying circular runway, and a platform centrally located within the lower end of said outer wall, substantially as described.

2. In a pin of the class described, the combination of an outer wall, an inner wall concentric with said outer wall and extending from a greater elevation than said outer wall and separated from said outer wall to provide a chamber between them, and a platform centrally positioned within

the lower end of said outer wall to provide a circular runway between said outer wall and said platform, substantially as described.

3. In a pin of the class described, the combination of an outer wall, an inner wall extending from a greater elevation than the lower end of said outer wall, upper and lower separating-rings between said walls, whereby said walls are spaced to provide a chamber adapted to contain a filling material, and a platform centrally located within the lower end of said outer wall, and between which and said outer wall a runway is provided, substantially as described.

700,950. MOTOR-VEHICLE. ARTHUR G. KRAM, Paris, France, assignor to Ste. Auto des Antennes Stabissements Fumard et Lovenor, Paris, France. Filed Aug. 9, 1901. Serial No. 71,517. (No model.)

Claim.—1. The combination with a motor-car having a motor-shaft, a drive shaft, and intermediate motion-transmitting mechanism, of a brake for said mechanism, an operating-lever of said brake mounted directly on the casing of said mechanism, and means for suspending said casing movably relatively to the framing of the car, whereby the wedging of the shaft of said mechanism in its bearings is avoided.

2. The combination with a motor-car having a motor-shaft, a drive shaft, and intermediate motion-transmitting mechanism, of a casing for said mechanism, and supports *a* and *b* for said mechanism connected to the framing of the car whereby the easy and rapid removal of the mechanism from the framing of the car may be effected.

3. The combination with a motor-car having a motor-shaft, a drive shaft, and intermediate motion-transmitting mechanism, of a casing for said mechanism, and supports *a* and *b* for said mechanism connected flexibly to the framing of the car whereby the easy and rapid removal of the mechanism from the framing of the car may be effected, and whereby the wedging of the shaft of said mechanism in its bearings is avoided.

4. The combination with a motor-car having a motor-shaft, a drive shaft, and intermediate motion-transmitting mechanism, of a brake for said mechanism, an operating-lever of said brake mounted directly on the casing of said mechanism, and supports *a* and *b* for said mechanism connected flexibly to the framing of the car whereby the easy and rapid removal of the mechanism from the framing of the car may be effected, and whereby the wedging of the shaft of said mechanism in its bearings is avoided.

700,951. CURTAIN-FIXTURE. ALBERT LEACH, Brighton, Mass. Filed May 22, 1901. Serial No. 61,421. (No model.)

Claim.—1. A curtain-fixture, having, in combination, a roller, a spindle, a spring for actuating said roller, and a friction device for retarding the rotation of the roller actuated by the spring and constructed and arranged to increase the friction as the tension of the spring increases, substantially as described.

2. A curtain-fixture, having, in combination, a roller, a spindle, a spring connecting the roller and spindle, stop devices connected to the roller and spindle for limiting their relative rotating movement under the tension of said spring, and means for relatively adjusting the roller and spindle to vary the tension of said spring without changing the relative position of said stop devices, substantially as described.

3. A curtain-fixture, having, in combination, a roller, a spindle, a spring connecting the roller and spindle, a friction device, and connections between the friction device and roller for actuating the friction device when the roller is rotated on the spindle, constructed and arranged to be rendered inoperative by the operator while the curtain is wound upon the roller, substantially as described.

4. A curtain-fixture, having, in combination, a roller, a spindle, a spring connecting the roller and spindle, a screw-threaded sleeve mounted on the spindle and connected to the roller, a traveling nut mounted on the sleeve and connected to the spindle, and means for disconnecting the

roller and sleeve to allow a rotation of the roller to adjust the tension of the spring, substantially as described.

5. A certain fixture, having, in combination, a roller, a spindle, a spring connecting the roller and spindle, a screw-threaded sleeve mounted on the spindle and connected to the roller, a traveling nut mounted on the sleeve, and a friction device acting to retard the rotation of the roller actuated by said nut, substantially as described.

6. A certain fixture, having, in combination, a roller, a spindle, a spring connecting the roller and spindle, a screw-threaded sleeve mounted on the spindle and connected to the roller, a traveling nut mounted on the sleeve, a friction device acting to retard the rotation of the roller actuated by said nut, and means for disconnecting the roller and sleeve, substantially as described.

7. A certain fixture, having, in combination, a roller, a spindle, a screw-threaded sleeve mounted on the spindle and connected to the roller, a traveling nut mounted on the sleeve, a spring connecting the roller and nut, and a friction device mounted on the spindle and arranged to be engaged and actuated by the nut to retard the rotation of the roller, substantially as described.

8. A certain fixture, having, in combination, a roller, a spindle, a friction device and disconnectable means between the friction device and roller for actuating the friction device when the roller is rotated on the spindle constructed and arranged to be disconnected by the operator while the certain is wound upon the roller, substantially as described.

700,952. HAND-SCREW. CHARLES E. LINDSEY and LOUIS E. CHRISTIAN, Chicago, Ill. Filed Aug. 12, 1901. Serial No. 71,405. (No model.)

Claim.—In a hand-screw, the combination with (filary) and clamping screws; of a fixed jaw having a swivelled engagement with said screws, and a movable jaw having a threaded engagement with said screws, the movable jaw comprising sections adapted to be moved toward and away from each other and into and out of engagement with the screws, a U-shaped yoke slidably mounted in parallel apertures in the jaw-sections, the intermediate portion of the yoke lying in a recess in one of the sections, a cam filarment between the ends of the arms of the yoke and adapted to force the sections together, expansive springs coiled around the arms of the yoke and acting in opposite directions on the movable jaw-sections, and an auxiliary expansive spring mounted between the projecting ends of the movable jaw.

700,958. CARTON. ALBERT V. LOUIS, Innapert, F. R., assignor of two-thirds to Fred L. Puchard, Brooklyn, Mass., and Henry S. Stator, Brooklyn, Mass. Filed Aug. 12, 1901. Serial No. 71,905. (No model.)

Claim.—1. As an article of manufacture, a carton consisting of two parts, A, B, of equal size, a hinged connection between the parts, a strip, D, fixed to one of the parts projecting beyond the same and arranged to enter the expansion part, and a fastener for the two parts consisting of a hooked member having its ends E projecting through the part A immediately below the strip D, substantially as described.

2. As an article of manufacture, a carton comprising two parts adapted to fit the one upon the other, a strip on the edge of one part projecting beyond the same, and a fastener for securing the parts together comprising a substantially V-shaped member having its apex offset and its free ends inserted through one of the parts of the carton and bent

down upon the inner face of the same, the other part of the carton having an opening therein for the reception of the offset portion of the fastener, substantially as described.

700,954. PRESSURE-REDUCING DEVICE. NATHANIEL LOWRANCE and JAMES G. BARNES, Boston, Mass., assignors to The Boston Chemical Fire Engine Manufacturing Company. Filed Apr. 21, 1900. Serial No. 12,700. (No model.)

Claim.—1. A pressure-reducing device comprising a casing having inlet and outlet chambers connected by a passage, a valve controlling said passage, an expansion-chamber external to the casing, a stem interposed between said chamber and the valve, and passing through the wall of the casing, a dash traversing said stem and connecting the interior of the expansion-chamber with the outlet-chamber, whereby the pressure in the expansion-chamber is controlled by that in the outlet-chamber, and means to bodily adjust said expansion-chamber axially of said stem.

2. A pressure-reducing device comprising a casing having a valve-seat located between inlet and outlet chambers, a valve operating in connection with said seat, a stem for operating said valve, said stem being separate from the valve, an expansion-chamber with separable walls controlling said stem and adapted to close the valve by the separation of said walls, a yoke or frame connected with the casing and forming an outer abutment for said chamber being detachably secured to said chamber, and means to bring the pressure of the outlet-chamber to the interior of said expansion-chamber.

3. A pressure-reducing device comprising a casing having a valve-seat located between inlet and outlet chambers, a valve operating in connection with said seat, a stem for operating said valve, said stem being separate from the valve, an expansion-chamber consisting of two plates connected at their edges and one of said plates connected to the stem, the said plates having a springiness normally moving them together, the separation of said plates causing the valve to close, a yoke connected with the casing and attached to the outer plate, and means to bring the pressure of the outlet-chamber to the interior of said expansion-chamber.

4. A pressure-reducing device comprising a casing having a valve-seat located between inlet and outlet chambers, a valve operating in connection with said seat, a stem for operating said valve, said stem being separate from the valve, an expansion-chamber consisting of two plates connected at their edges and one of said plates connected to the stem, the said plates having a springiness normally moving them together, a yoke connected with the casing and attached to the outer plate, and a dash traversing said stem and connecting the outlet-chamber with the expansion-chamber, whereby the pressure in the expansion-chamber is controlled by that in the outlet-chamber.

5. A pressure-reducing device comprising a casing having a valve-seat located between inlet and outlet chambers, a valve operating in connection with said seat, a stem for operating said valve, an expansion-chamber with separable walls controlling said stem, a yoke or frame connected with the casing and forming an outer abutment for said chamber, means to bring the pressure of the outlet-chamber to the interior of said expansion-chamber, and means to adjust said yoke on the casing.

700,955. SMOKE AND CINDER CONVEYER. HARRY S. LOON, Bath, Me. Filed Mar. 7, 1901. Serial No. 59,199. (No model.)

Claim.—1. The conveyor herein shown and described consisting of the smoke-stack, the section of pipe leading from the smoke-stack, the funnel connected to the section for drawing in air, and the series of sections connected to the main section by a flexible connection, comprising the flexible tubes, the bands connecting the outer ends of the tubes to the conveyor-sections, the rings which move the inner ends of the flexible tubes having the flanges bolted together, the bands which secure the inner ends of the tubes to the flanged rings, and the coils arranged in the flexible tubes and retained in place by the flanged rings and the ends of the conveyor.

2. The combination of a smoke-stack provided at its front with an opening and an open plate, a pivoted damper mounted within the stack above said opening and plate, a lever extending from one side of said damper and carrying a weight, a crank extending from the opposite side and having bearing in the stack, said crank and lever being bent in opposite directions, and a connection attached to said crank and leading to the ash, all substantially as shown and described and for the purpose specified.

700,956. WINDOW. ARTHUR LOONAN, West New York, N. J. Filed Sept. 11, 1901. Serial No. 78,000. (No model.)

Claim.—1. In a window, the combination, with a window-casing, a window-frame fitting into said casing and hinged at one side thereto, slidable sashes arranged in said frame, and means for suspending each sash, consisting of guide-pulleys located respectively in the window-casing and on the window-frame, each weight and single end-cord attached at their ends to opposite sides of the sashes and guided over the pulleys of the casing and frame, substantially as set forth.

2. In a window, the combination, with a window-casing, of a window-frame hinged at one side to said casing, slidable sashes in said frame, and means for suspending said sashes, consisting of pulleys suitably arranged on said frame, and depending twin pulleys arranged in said window-casing, end-cords passing over said pulleys, and counterbalancing-weights for suspending said sashes, substantially as set forth.

3. In a window, the combination, with a window-casing, a window-frame hinged at one side to said casing, slidable sashes in said window-frame, pulleys arranged on the top of said frame adjacent each side, pulleys arranged in the hinged side of the frame adjacent the top thereof, depending twin pulleys provided in the window-casing opposite the last-mentioned pulleys in the frame, counterbalancing-weights provided with guide-pulleys and end-cords passing over the pulleys of the weight, casing and frame, and being attached to the opposite sides of the sashes, substantially as set forth.

4. In a window, the combination, with a window-casing, of a window-frame hinged at one side to said casing, slidable sashes in said frame, suitable pulleys arranged in the top and side of said frame, twin pulleys arranged in said window-casing, a box for housing said pulleys and journaled one above the other therein, a stationary bearing in said casing, one side of said bearing diverging from the pivotal center of the pulley-box.

counterbalancing-weights, one for each sash, and a single end-cord guided over pulleys and adapted to suspend each weight and sash, substantially as set forth.

700,957. SAFETY ATTACHMENT FOR VEHICLE. JAMES P. LOON, Bath, Me., assignor to ARTHUR LOONAN, Bath, Me. Filed Apr. 1, 1902. Serial No. 100,000. (No model.)

Claim.—A safety attachment for vehicles, comprising in combination with the shaft, a safety-strap having connections on its ends carrying eyes, straps passing through said eyes and engaging the shaft for adjusting the tension of said safety-strap, loops carried by the safety-strap adjacent its ends, and holdback-straps engaging in said loops and secured to the forward portion of the shaft, substantially as described.

700,958. CONTINUOUS-CIGARETTE MACHINE. FRANK J. LOONAN, Watertown, Conn. Filed May 10, 1901. Serial No. 59,199. (No model.)

Claim.—1. In a continuous-cigarette machine, the combination, with the belt-wheel A, A', and the flat belt D driven thereby, of the grooved shaping-wheel G arranged to press the filler directly upon the naked surface of the flat belt over the corner of the wheel A, means for stripping the tobacco from the belt and means for leading a tape and cigarette-wrapper beneath the filler adjacent to the wheel G when delivered from the belt, means for feeding the tobacco in the belt, and means operated upon

the surface of the belt for compressing and shaping the tobacco into an angular rod and delivering it to each shaping-wheel and belt, the whole operating to form a half-round filler and deliver the same to the wrapper and tape.

2. In a continuous-cigarette machine, the combination, with the belt-wheels A, A', and the flat belt B driven thereby, of two horizontal angularly-grooved wheels C, C', adapted to form a diamond-shaped filler-rod upon each belt, guides D to confine the tobacco delivered to the belt, the flat-faced presser-wheel E between the guides just preceding the horizontal wheels, guides F upon the belt beyond each horizontal wheel to determine the width of the filler-rod, the vertical round-grooved wheel G operating upon the naked surface of the belt between each guide over the center of the belt-wheel A to give a half-round shape to the filler-rod, the shoe F' for stripping the flat side of the filler-rod from the belt, and means for leading a tape and cigarette-wrapper beneath the filler adjacent to each shoe.

3. In a continuous-cigarette machine, the combination, with the belt-wheels A, A', and the flat belt B driven thereby, of two horizontal angularly-grooved wheels C, C', adapted to form a diamond-shaped filler-rod upon each belt, guides D to confine the tobacco delivered to the belt, the flat-faced presser-wheel E between the guides just preceding the horizontal wheels, guides F upon the belt beyond each horizontal wheel to determine the width of the filler-rod, the vertical round-grooved wheel G operating upon the naked surface of the belt between each guide over the center of the belt-wheel A to give a half-round shape to the filler-rod, a guard-plate H over the junction of the horizontal wheels C, C', and extending between the wheels E and G to confine the tobacco to the space between the horizontal wheels, the shoe F' for stripping the flat side of the filler-rod from the belt, and means for leading a tape and cigarette-wrapper beneath the filler adjacent to each shoe.

4. In a continuous-cigarette machine, the combination, with belt-pulleys and a flat-belt, of the horizontal angularly-grooved wheels C, C', meeting upon the surface of each belt, guides D for the tobacco upon the belt, the flat-faced presser-wheel E between the guides just preceding the horizontal wheels, guides F upon the belt beyond each horizontal wheel to determine the width of the filler-rod, a shaft for rotating the wheel E with bracket-bearing I projected over one of the horizontal wheels, a swinging arm J journaled upon each bearing and having the grooved wheel G journaled thereon and fitted between the guides F, and the guard-plate H fitted between the wheels E and G over the horizontal wheels and attached to the arm J, and means to secure each arm when adjusted, whereby the wheel G and the guard-plate may be lifted from the horizontal wheels or adjusted in their working position.

5. In a continuous-cigarette machine, the combination, with the belt-wheels A, A', and the flat belt B driven thereby, of two horizontal angularly-grooved wheels C, C', adapted to form a diamond-shaped filler-rod upon each belt, guides D to confine the tobacco delivered to the belt, the flat-faced presser-wheel E between the guides just preceding the horizontal wheels, with shaft i extending backwardly, the bearing I to contain each shaft, the arm J pivoted upon each shaft, the round-grooved wheel G journaled upon each arm and arranged to press the tobacco upon the naked surface of the belt, the gear-wheels upon the said arm connecting the shaft i with the grooved wheel G, a shoe for stripping the filler formed by the wheel G upon the belt, and means adjacent to each shoe for leading a tape and cigarette-wrapper beneath the filler.

6. In a continuous-cigarette machine, the combination, with the traveling flat-belt B, and the two horizontal angularly-grooved wheels C, C', arranged to form a diamond-shaped filler-rod upon each belt, of the guides D to confine the tobacco delivered to the belt, the flat-faced presser-wheel E between each guide close to the junction of the horizontal wheels with shaft E' extending backwardly, the bearing I to contain each shaft, the arm J pivoted upon each shaft, the round-grooved wheel G journaled upon each arm and fitted to press the tobacco upon the belt as it is discharged from the grooved wheels C, C', gearing upon the said arm connecting the shaft E' with each grooved wheel, the guard-plate H contained upon the said arm and held over the junction of the wheels C, C', between the wheels E and G, and means for securing the arm when the grooved wheel and the guard-plate are properly adjusted to the wheels C, C', substantially as herein set forth.

7. In a continuous-cigarette machine, the combination, with the belt-wheels A, A', and the flat belt B driven thereby, with the vertical grooved wheel G arranged over the center of the pulley A, and horizontal grooved wheels C, C', having their edges upon the surface of the belt just in advance of the wheel G, whereby the shafts c of said grooved wheels C, C', are at one side of the shaft a carrying the pulley A, the bearing c' of the shaft c adjustable to and from the wheel C', and the shaft a provided at opposite sides of the wheel A with the spiral gears a', and the vertical shafts c having the spiral gears c' connected with the spiral gears a', whereby the grooved wheels C, C', are driven directly from the shaft of the belt-wheel.

700,959. PROCESS OF UNITING BATTERY-PLATES. WILLIAM F. J. LOVI, Chicago, Ill., assignor of two-thirds to Hans Adam Schlecter and John Henry George Lutz, Chicago, Ill. Filed Feb. 14, 1901. Serial No. 47,575. (No specimens.)

Claim.—The process of joining metal plates by a connecting-bar which consists in first directing a fusing-blast into an inclosed space, and against the surfaces of said plates, which are exposed to the blast entering said space, to fuse the exposed parts of the plates, confining the fused metal in contact with the parts of said plates from which the metal was fused and thereafter pouring into said space molten metal which unites with the fused metal of the plates and forms the connecting-bar.

700,960. LOADING ATTACHMENT FOR HAND-TRUCKS. THOMAS J. LYNN, Chicago, Ill. Filed Feb. 28, 1901. Serial No. 48,000. (No model.)

Claim.—1. An attachment for hand-trucks comprising a lever and means for pivotally attaching said lever to the truck-frame, said lever being adapted at its forward end to bear upwardly against the truck-frame, a spring engaging said lever and adapted to throw the lever upwardly when not in use, and a stop for limiting the upward throw of the lever under the action of said spring.

2. The combination with a hand-truck, of a lever pivoted between its ends to said truck-frame and bearing downwardly on the axle of the truck, which latter constitutes the fulcrum of the lever, said lever extending forwardly under and bearing upwardly against the frame of the truck and extending rearwardly from its fulcrum in position to be engaged by the feet of the person using the truck, a spring applied to the lever for holding the same in its upposition position and a stop for limiting the upward movement of the lever.

3. The combination with a hand-truck, of a pivoted lever adapted to bear downwardly against the axle which latter constitutes a fulcrum for the lever, said lever extending at its forward end under and bearing upward against the truck-frame, and extending at its rear end in position to be engaged by the feet of the operator, a spring applied to the lever for holding the same in its upposition position, and a stop for limiting the upward movement of said lever with the free end thereof separated a distance from the truck-frame, to be readily engaged by the feet of the operator.

700,961. HEATING OR COOKING ATTACHMENT FOR STOVES. JOHN P. LYNN, Louisville, Mo. Filed Mar. 11, 1900. Serial No. 57,000. (No model.)

Claim.—1. In a heating or cooking attachment for stoves, the combination with a suitable oven or cooking-receptacle, of a support therefor, said support comprising a metal disk and a plurality of hangers extending up therefrom and terminating in hooks, said hangers being formed of strips of metal extending under the metal disk or support and secured thereto, substantially as and for the purpose described.

2. A heating or cooking attachment for stoves, comprising a support having upwardly-extending hooked hangers to engage the rim around the stove-opening, an oven or cooking-receptacle adapted to rest upon the support and provided with a swingable bail and an upwardly-extending rest therefor, and a suitable rack to rest upon the bottom of the oven or receptacle, substantially as and for the purpose set forth.

700,962. ANTRALINO-BEL. JOHN J. HANNEY, Attorney, Ind.
Filed Nov. 22, 1921. Serial No. 92,594. (No model.)

Claim.—1. An annealing-box including a stand or bottom provided with lifting wings or legs formed of projecting portions of the stand-plate and extending from the upper extremities of the stand sides in parts equal in thickness therewith and doubled over toward the sides, whereby combined lifting and reinforcing devices are provided, and a box-body.

2. An annealing-box stand formed of a blank having projecting portions at opposite edges thereof, the projecting portions bent over from the edges of the stand sides and forming combined lifting wings or legs and reinforcing-ribs for the stand sides.

3. An annealing-box stand and lifting-ribs thereof composed of a single malleable plate-blank having projecting portions at opposite edges thereof, all of uniform gage thickness, the projecting portions bent over in the form of inverted troughs.

4. In an annealing-box stand, the combination of the stand-body having the bottom and sides thereof composed of metal of uniform gage thickness, two of the sides having projecting portions extending from the edges thereof, and the lifting-wings consisting of said projecting portions turned over immediately at the edges of said sides.

5. In an annealing-box, the combination of the box-body, the stand-body formed of the blank having the projecting wings extending from opposite edges thereof, the lifting wings or legs consisting of said projecting wings bent over from said edges in the form of inverted troughs, and the supporting-legs, substantially as set forth.

700,968. BLANK-FURNACE TOP. PATRICK HENRIK, Louisville, Ohio.
Filed Apr. 12, 1921. Serial No. 92,595. (No model.)

Claim.—1. A blast-furnace having a shaft, a globe-shaped top on said shaft providing a substantially globe-shaped chamber having an unobstructed annular passage to the furnace-chamber, and a hopper projecting through said top and extending down into the globe-shaped chamber with its discharge and below the largest diameter of said globe-shaped chamber, whereby an enlarged space is provided to allow for the expansion of gases in an explosion.

2. A blast-furnace having a shaft, a globe-shaped top springing from said shaft providing a substantially globe-shaped chamber having an unobstructed annular passage to the furnace-chamber, a hopper projecting through said top and extending downward into the globe-shaped chamber

with its discharge and below the largest diameter of said globe-shaped chamber, whereby an enlarged space is provided to allow for the expansion of gases in an explosion, a gas-port extending through said globe-shaped top, and a downcomer connected to said port.

3. A blast-furnace having a masonry shaft, a metal shell around said shaft, a globe-shaped top springing from said shell and providing a substantially globe-shaped chamber having an unobstructed annular passage to the furnace-chamber, and a hopper projecting through said top and extending down into the globe-shaped chamber with its discharge and below the largest diameter of said globe-shaped chamber, whereby an enlarged space is provided to allow for the expansion of gases in an explosion.

4. A blast-furnace having a masonry shaft, a metal shell around said shaft, a globe-shaped top springing from said shell and providing a substantially globe-shaped chamber having an unobstructed annular passage to the furnace-chamber, a hopper projecting through said top and extending downward into the globe-shaped chamber with its discharge and below the largest diameter of said globe-shaped chamber, a gas-port extending through said globe-shaped top, and an explosion-door at the outer end of said gas-port.

5. A blast-furnace having a masonry shaft, a metal shell around said shaft, a globe-shaped metal top springing from the outside of said metal shell below the top thereof, and a refractory lining for said globe-shaped top, the lower edge of said lining projecting down between the globe-shaped metal top and the metal shell for the stack and lying outside the latter, whereby free expansion of the masonry shaft is permitted.

6. A blast-furnace having a masonry shaft, a metal shell around said shaft, the top of said shaft being formed of blocks having lips which are hooked over said shell, a globe-shaped metal top springing from the outside of said metal shell below the top thereof, and a refractory lining for said globe-shaped top, the lower edge of said lining projecting down between the globe-shaped top and metal shell for the stack and lying out of contact with the overhanging lips of the blocks on the top of the shaft.

7. A blast-furnace having a masonry shaft provided with an inclined upper flue, a metal shell around said shaft, a globe-shaped top springing from said shell and providing a substantially globe-shaped chamber having an unobstructed annular passage to the furnace-chamber, a hopper projecting through the top and extending downward in the globe-shaped chamber with its discharge and below the largest diameter of said globe-shaped chamber, a gas-port extending through said globe-shaped top and substantially in line with the inclined upper flue of the masonry shaft, and an explosion-door at the outer end of said gas-port.

8. A blast-furnace having a masonry shaft the top of which is formed by one or more tiers of hollow cast-metal blocks, said blocks being below the discharge end of the hopper and the gas-ports.

9. A blast-furnace having a masonry shaft the top of which is formed by one or more tiers of interlocking hollow blocks.

10. A blast-furnace having a masonry shaft the top of which is formed of closed hollow cast-metal blocks provided with inclined upper flues, said blocks being below the discharge end of the hopper and the gas-ports.

11. A blast-furnace having a masonry shaft, and a metal shell around said shaft, the top of said shaft being formed of hollow blocks having lips which hook over said shell.

700,964. WORK-HOLDING ATTACHMENT FOR DRILLS.
GEOFFREY E. HUNTER, Worcester, Mass. Filed Dec. 20, 1921. Serial No. 92,596. (No model.)

Claim.—1. In a device of the class described, the combination of a table or plate and a rotary work-holder having a work-receiving socket, said parts being arranged so that by turning the rotary holder to bring its socket over the plate or table, a piece to be drilled may be first placed

In said outlet and then moved along over the table or plate to be presented in proper position to be acted upon by a drill, after which the continued rotation of the holder will carry the same off from the plate or table so that it may drop down through the outlet in the rotary holder.

2. In a device of the class described, the combination of a rotary holder, and stopping device therefor, comprising a holding-stop arranged to prevent the holder to rotate past the same, and a positioning-spring tending to turn the holder back against the holding-stop.

3. In a device of the class described, the combination of a rotary holder, and stopping device therefor, comprising a holding-stop arranged to prevent the holder to rotate past the same, a positioning-spring tending to move the rotary holder back against the holding-stop, and means for moving the positioning-spring out of the path of the rotary holder.

4. In a device of the class described, the combination of a rotary holder comprising a plurality of arms, a holding-stop permitting the arms of the rotary holder to rotate past the same, a positioning-spring tending to move the rotary holder back against the holding-stop, and a cam for lifting the end of the positioning-spring out of the path of the rotary holder, to prevent the same to fly back into position to cooperate with a succeeding arm of the rotary holder.

5. In a device of the class described, the combination of a rotary holder having extending arms, each of which is provided with a work-receiving outlet, and stopping device therefor, comprising a holding-stop arranged to prevent the rotary holder to rotate past the same, and a positioning-spring arranged to engage the forward side of each piece of work as the same is brought into position, whereby said positioning-spring tends to turn the rotary holder back against the holding-stop, and also serves to guide the piece of work about to be acted upon.

700,965. PICKER-STICK BUFFER FOR LOOMS. FRANK A. HALL, Methuen, Mass., assignor of one-half to Grosvenor E. Hanson, Methuen, Mass. Filed Oct. 20, 1901. Serial No. 98,501. (No model.)

Claim.—1. A buffer device for the picker-sticks of looms consisting of a pneumatic rubber buffer of hemispherical form, a holder therefor, a convex button contacting with the crown of the buffer, a flexible strap-hanger attached to the back of the button having branches extending over said buffer and fastened to the holder thereof around the base of the buffer, a leather disk forming a backing for said strap and a curved centrally fastening together the button, the strap and the leather disk.

2. A buffer device for the picker-sticks of looms consisting of a pneumatic rubber buffer of hemispherical form, a holder therefor, a convex button contacting with the crown of the buffer, and a strap-hanger for the button having branches extending over said buffer and fastened to the holder around the base of the buffer, a disk forming a backing for the strap to receive the impact of the picker-stick and means for centrally fastening the impact-disk to the button and its strap-hanger.

3. In a loom and in combination, the race-ly, the picker-stick, a bracket depending from the race-ly, a hemispherical rubber buffer seated in the bracket, a button consisting of a convex button contacting with the crown of the rubber buffer, a flat leather surface forming a backing for the button, a strap covering the buffer and having buttonholes for fastening it to and around the rim of the bracket, and means for securing the button and the impact flat surface centrally to the strap.

4. A button-buffer device for the picker-sticks of looms consisting of a pneumatic rubber buffer of hemispherical form, a convex knob, a leather disk or flange forming a backing for the knob, and a leather strap-holder for the knob and the disk permitting movement thereof in a direction corresponding to the direction of movement of the picker-stick.

5. A button for receiving the impact of the picker-sticks of looms consisting of a convex knob, a leather disk or flange complementing the back of the knob and a flexible hanger or holder between the knob and the disk, and means for centrally fastening the parts together.

6. In a loom and in combination with the race-ly and the picker-stick, of a buffer device consisting of a bracket on the ly, an arched pneumatic rubber buffer, a convex button-button complementing the crown of the rubber buffer and a flexible hanger or holder for maintaining the convex surface of the buffer and of the button in contact under the impact of the picker-stick.

700,966. SEEDER. GEORGE HENSHAW and WILLIAM FARRER, Middletown, Ohio; said Henshaw assignor to said Farrer. Filed Dec. 9, 1901. Serial No. 98,502. (No model.)

Claim.—1. A seeding mechanism, comprising a seed-cup, having a discharge-passage leading therefrom, the wall of the said cup which is immediately above the entrance of the outlet-passage extending outwardly over the said passage so that seed which do not enter the passage cannot be caught and crushed but are free to yield and move along the seed-cup wall above the passage-entrance, substantially as described.

2. A seeding device, comprising a seed-cup having a discharge-passage leading therefrom, a guarding projection extending slightly into said passage at the entrance thereof, so that seed which are able to pass the said projection will easily travel through the said passage-way without danger of clogging, substantially as described.

3. A seeding mechanism, comprising a seed-cup having an outlet or discharge passage leading therefrom, means for carrying seed from the cup through said passage, the said passage-way increasing slightly in size from its inner end outwardly so that seed which once enter said passage have no chance of clogging therein, substantially as described.

4. A seeding device, comprising a cup having a discharge outlet-passage leading therefrom, a seed-wheel for carrying seed through said passage, the wall of said passage which opposes said wheel being rounded to prevent the possibility of seed being caught therein, substantially as described.

5. A seeding device, comprising a seed-cup having an outlet-passage leading from the lower end thereof, the said cup being enlarged in a conical manner above the entrance of said discharge-passage, and a seed-wheel for carrying the seed from the cup, the beveled portion of the cup preventing any clogging of the seed and causing them to be thoroughly cleaned therein by the action of the seed-wheel, substantially as described.

6. A seeding device, comprising a seed-cup, an outlet-passage leading therefrom, a seed-wheel journaled within the cup and formed with a flange having a curved inner seed-engaging surface, the said flange being provided with means for engaging the seed and carrying the same through the discharge-passage of the cup, substantially as described.

7. A seeding device, comprising a seed-cup formed with outlet-passages leading therefrom, the said passages having curved inner surfaces, a seed-wheel arranged so that its periphery will travel through said passages, the said seed-wheel being formed with laterally-extending peripheral flanges formed with curved inner surfaces opposing the curved inner surfaces of the discharge-passages, the said seed-wheel flanges being formed with a series of radially-arranged grooves or depressions in their curved surfaces for engaging the seed more positively, substantially as described.

8. A seeding device, comprising a seed-cup formed with an enlarged portion at its lower end having a curved inner surface, a discharge passage-way leading from said enlarged portion, a guarding projection at the entrance of the passage-way arranged to divide the seed, permitting some to pass into the passage-way and others to travel around upon the inner curved surface of the enlarged portion of said cup, and a seed-wheel for continuously agitating the seed in the cup and carrying them out through the discharge passage-way, substantially as described.

700,967. METHOD OF EXTINGUISHING FIRE. JOHN R. MOORE, New York, and FRED M. HART, Brooklyn, N. Y.; said Moore assignor to the Clayton Fire Extinguishing & Distributing Company, a Corporation of West Virginia. Filed May 22, 1901. Serial No. 61,548. (No model.)

Claim.—1. The method of extinguishing fire in cotton-bales and similar combustibles, which consists in confining the combustibles in air-tight compartments, and producing and maintaining under pressure therein, an atmosphere containing a gas which is a non-supporter of combustion.

2. The method of extinguishing fire in cotton-bales and similar combustibles, which consists in confining the combustibles in air-tight compartments, forcing into the same a mixture of air and a gas which is a non-supporter of combustion until a pressure is produced therein and maintaining such pressure until the fire is extinguished.

3. The method of extinguishing fire in cotton-bales and similar combustibles, which consists in confining the combustibles in an air-tight compartment, and charging, under pressure, each compartment with a mixture of air and carbon-dioxide gas, as set forth.

4. The method of extinguishing fire in cotton-bales and similar combustibles, which consists in confining the combustibles in air-tight compartments, and, in case of fire therein, injecting into the compartments carbon dioxide from a supply of the same stored under pressure for immediate use, and then generating a further supply of carbon dioxide and forcing it together with air into the compartments as so to produce and maintain a pressure of gas therein, as set forth.

700,888. COOKING-BUCKET. JAMES H. McFARLAND, JR., San Francisco, Cal. Filed Aug. 13, 1901. Serial No. 71,999. (No model.)

Claim.—1. A cooking-bucket comprising a body portion having a groove in its inner wall and provided with eyes adjacent thereto, a strainer-plate adapted for engagement with the groove, and latches each including spaced legs having a connecting spring portion, one leg of each latch being attached to the plate and the other leg having a terminal hook for engagement with the corresponding eye of the bucket, said plate, eyes and latches being entirely within the bucket to permit of application of a lid thereto.

2. A cooking-bucket having an inner groove in its wall and provided with eyes within the bucket and adjacent to the groove, and a strainer-plate engaged removably with the groove and having means for holding the strainer-plate yieldably in the groove, said means being within the bucket and removably engaged with the eyes.

3. A cooking-bucket comprising a body portion having a groove in its inner wall and provided with eyes, and a strainer-plate adapted for engagement of an edge thereof in the groove and having spring-latches attached thereto and each including spaced legs, one of which is attached to the plate and the other of which is removably engaged with the corresponding eye, said legs being connected by a resilient loop and the latches being arranged to lie entirely within the bucket to permit of application of a cover thereto.

700,889. STOP-MOTION FOR LOOMS. GRAMMIE R. WILLIAMS, Paterson, and JAMES R. JACOBSON, North Hudson, N. J. Filed Dec. 24, 1901. Serial No. 71,999. (No model.)

Claim.—1. In a stop-motion mechanism for narrow-loom looms, the combination, with the bottom, of a reciprocating part on the bottom movable transversely of the movement thereof, an elastic flexible member adapted to actuate the power-controlling mechanism of the loom, a detent normally holding said member retracted, and means, movable with said reciprocating part, for actuating said detent to release said member, substantially as described.

2. In a stop-motion mechanism for narrow-loom looms, the combination, with the bottom, of a reciprocating part on the bottom movable transversely of the movement thereof, an elastic flexible member adapted to actuate the power-controlling mechanism of the loom, a hook normally holding said member retracted, and engageable blocks, one of said blocks being movable with said reciprocating part and the other being connected to said hook, substantially as described.

3. In a stop-motion mechanism for narrow-loom looms, the combination, with the bottom, of a reciprocating part on the bottom movable transversely of the movement thereof, an elastic flexible member adapted to actuate the power-controlling mechanism of the loom, a hook normally holding said member retracted, and engageable blocks, one of said blocks being movable with said reciprocating part and the other being connected to said hook, the free end of one block which is adjacent the other having step-like projections, substantially as described.

4. In a stop-motion mechanism for narrow-loom looms, the combination, with the bottom, of a reciprocating part on the bottom movable transversely of the movement thereof, an elastic member adapted to actuate the power-controlling mechanism of the loom, a detent normally holding said member retracted, and means, movable with said reciprocating part, for actuating said detent to release said member, substantially as described.

5. In a stop-motion mechanism for narrow-loom looms, the combination of two parts adapted to impinge the one against the other to effect the stopping, one of said parts being adapted to move in a curved line and one of said parts, also, having the free thereof adjacent the other part provided with steps arranged in a curved line, substantially as described.

700,890. ADJUSTABLE SPEED-GEAR. JAMES H. McFARLAND, JR., San Francisco, Cal., assignor of one-half to John Breckman, San Francisco, Cal. Filed Sept. 22, 1904. Serial No. 71,999. (No model.)

Claim.—1. A driving mechanism comprising a shaft, a sleeve or said shaft, helical guides on said sleeve and of varying pitch, a clutch mechanism engaging said guides, and connections of said mechanism with a prime mover whereby the clutch is reciprocated to drive the sleeve and shaft.

2. In a driving mechanism, the combination of a shaft, a sleeve slidable thereon and turnable therewith, helical guides varying in pitch between their ends upon said sleeve, and a clutch mechanism engaging said guides and reciprocable in the line of the shaft.

3. In a driving mechanism, the combination of a shaft, a sleeve slidable thereon and turnable therewith, helical guides of varying pitch on said sleeve, part of said guides yielding to the right and the remainder to the left about said sleeve, and a clutch mechanism engaging said guides and adapted to reciprocate in the line of the shaft.

4. In a driving mechanism, the combination of a shaft, a sleeve slidable thereon and turnable therewith, helical guides of varying pitch on said sleeve, a clutch mechanism reciprocable in the line of the shaft, said clutch having members engaging said guides, said members acting alternately to drive the sleeve and to reverse freely therewith, and means for shifting said sleeve within said clutch mechanism.

5. In a driving mechanism, the combination of a shaft, a sleeve slidable thereon and turnable therewith, helical guides of varying pitch on said sleeve, a clutch mechanism including said sleeve, and reciprocable

thereon, means by which said clutch is prevented from turning, and connections between said clutch and guides whereby the sleeve and shaft are revolved.

6. In a driving mechanism, the combination of a shaft, a sleeve thereon, helical guides of varying pitch on said sleeve, a clutch including and reciprocable upon said sleeve, means by which said clutch is prevented from turning, said clutch comprising rotatable members, pins mounted in said members, said pins adapted to engage the helical guides to drive the sleeve and shaft when the clutch is reciprocated.

7. In a driving mechanism, the combination of a shaft, a sleeve thereon, helical guides of varying pitch on said sleeve, a clutch including and reciprocable upon said sleeve, said clutch comprising a frame, rotatable grip members in said frame, recesses on the inner periphery of said members, pins loosely mounted in said recesses, and said pins adapted to engage the helical guides to drive the sleeve and shaft.

8. In a driving mechanism, the combination of a shaft, a sleeve thereon, helical guides of varying pitch on said sleeve, a clutch including and reciprocable upon said sleeve, means by which said clutch is prevented from turning, said clutch having grip members rotatable in opposite directions, and pins carried by said members and adapted to engage the helical guides to drive the sleeve when the clutch is reciprocated.

9. A driving mechanism consisting in combination of a shaft, a sleeve slidable thereon and revolvable therewith, helical guides on said sleeve, said guides having a uniform progressive variation in pitch between their ends, a clutch including and reciprocable upon said sleeve, means by which said clutch is prevented from turning, rotatable grip members in said clutch and means upon said members for engaging said helical guides to drive the sleeve and shaft when the clutch is reciprocated, and means by which said sleeve may be moved upon the shaft to bring sections of said guides of greater or less pitch within the scope of the clutch.

10. A driving mechanism comprising a shaft, a sleeve thereon, said sleeve and shaft revolvable in unison, one of said members slidable in relation to the other, helical guides of varying pitch on said slidable member, and a reciprocable clutch mechanism engaging said guides.

700,971. MASON'S PLUMB AND LEVEL. ANDREW L. MCKEY, HOLM, Cleveland, Ohio, assignor of one half to Charles F. Thomas, Cleveland, Ohio. Filed Mar. 7, 1901. Serial No. 80,192. (No model.)

Claim.—1. The combination of a mason's plumb-board with an opening therethrough containing a pivoted lever, a spirit-level attached to and supported by one end of the lever, a transverse screw with a nut adapted to engage the opposite end of the lever and swing it on its pivot and a thumb-wheel on the screw lying in the opening of the board and accessible from both sides thereof.

2. The combination of a mason's plumb-board having an aperture therethrough, a frame B, secured in said aperture, a bifurcated lever C, pivoted between the sides of said frame and carrying a spirit-level E, in its forks above the pivot, a transverse screw mounted in the frame and

provided with a thumb-wheel, with a threaded sleeve on the screw and a plate G, slidably secured to the lower end of the lever and pivotally connected to the threaded sleeve substantially as heretofore set forth.

3. The combination of a mason's plumb-board having an aperture therethrough, a frame B, secured in said aperture, a bifurcated lever C, pivoted between the sides of said frame and carrying a spirit-level E, in its forks above the pivot, a transverse screw mounted in the frame and provided with a thumb-wheel, a threaded sleeve on the screw, a plate G, slidably secured to the lower end of the lever and pivotally connected to the sleeve, with a graduated indicated scale on each outer face of the frame B, and pointers attached to the lever with their free ends adjacent to the said scales, substantially as heretofore set forth.

4. The combination of a mason's plumb-board having an aperture therethrough, a frame B, secured in said aperture, a lever pivoted between the sides of said frame and carrying a spirit-level, a transverse screw mounted in the frame and provided with a thumb-wheel, a threaded sleeve on the screw with a pivoted sliding connection to the lower end of the lever, a graduated indicating-scale on each outer face of the frame B, and pointers attached to the lever having their free ends adjacent to the said scales, with metallic side plates L, to inclose the aperture in the board, each provided with an opening for the thumb-wheel and also glass openings before the spirit-level and the graduated scales, substantially as heretofore set forth.

700,972. APPARATUS FOR LIXIVIATING ORES. FARR HAWK, Argentine, Kans. Filed Apr. 2, 1904. Serial No. 80,193. (No model.)

Claim.—1. In a lixiviating apparatus, a lixiviating-column adapted to be filled with a leaching solution, and having a series of superimposed

and inclined heads and rings, alternating and preventing oppositely-inclined surfaces for the downward passage of air thereover, the said heads and rings being numerously perforated to permit the upward passage of gas therethrough, as and for the purpose set forth.

2. In a lifting apparatus, a lifting-column having a series of superimposed and inclined surfaces with means for feeding the air in at the top and withdrawing the sludge at the bottom, the said inclined surfaces having numerous perforations adapted to permit the upward flow of gas therethrough, together with an inflow for the liquid at the bottom and its discharge at the top, and an air or gas injecting device admitting air or gas to the column below the perforated surfaces, whereby there is a down feed of the air over the perforated and inclined surfaces within the lifting column, and an uprising of the air or gas through the perforations of the inclined surfaces and a successive passage of the same through the several layers of ore within the lifting column.

3. In a lifting-column a funnel-shaped ring in combination with a conical head supported in line with the ring, and with an open passage between the head and the ring and down through the center of the latter, the said head and ring having numerous perforations adapted to permit the upward passage of gas therethrough, substantially as and for the purpose set forth.

4. In a lifting-column, a numerously-perforated funnel-shaped ring in contact with the column-wall, in combination with a conical numerously-perforated head, and connecting parts therefor, all integral, the head-section being centrally located with respect to the opening through the ring-section, and with an open channel between the head and the ring and down through the center of the latter, substantially as and for the purpose set forth.

5. A lifting-column having a series of perforated and inclined surfaces or partitions located in the middle or lower part thereof and an upper section without such partitions, in combination with means for the inflow of the liquid at the bottom and its discharge at the top, together with means for the injection of air or gas into the bottom of the column, and a conducting pipe for said air or gas into the bottom of the column, and a conducting-pipe for said air or gas through the upper section of the column, whereby ore particles carried up in suspension by the agitated current of liquid settle out therefrom in the column below the liquid over-flow, as and for the purpose set forth.

700,978. TYPE-WRITING MACHINE. JAMES E. HARRIS, Buffalo, N. Y., assignor to the Wagner Typewriter Company, New York, N. Y., a Corporation of New York. Filed Apr. 28, 1901. Serial No. 87,008. (No model.)

Claim.—1. In a type-writing machine, the combination, with the carriage having a platen and a guide in the rear of the platen and at a higher level than the same, a copying-ribbon and a duplicate paper strip passing from said guide to the platen, additional guiding means for the paper and ribbon located in the rear of said guide and at a lower level

than the same, whereby the paper and ribbon will be kept in close contact with each other from the guide to the platen, and means for feeding the paper and the copying-ribbon.

2. In a front-strike type-writing machine the combination of a platen, a platen-carriage, an adjustable paper-supply reel operatively connected to travel with said carriage, an adjustable take-up reel operatively connected to travel with the carriage and situated on a higher horizontal plane than the supply-reel, whereby the operator will have an unobstructed view of the written matter as the paper passes from one reel to another, laterally-adjustable guide to said reels to accommodate different widths of paper, means for automatically turning the take-up reel as the paper is fed forward and means for supporting said reels independently of the carriage.

700,974. PUMPING-ENGINE. HERMAN FRIEDMAN, South Brooklyn, N. Y., assignor of one-half to F. W. Oshitt and Son, South Brooklyn, N. Y. Filed May 20, 1901. Serial No. 62,698. (No model.)

Claim.—1. A duplex pumping-engine comprising a series of water-cylinders and pistons therein and a series of steam-cylinders and pistons therein, each water-piston connected with a steam-piston and ducts controlled by said pistons, one steam-piston controlling the ducts leading to and from the other steam-piston.

2. A duplex pump comprising two series of cylinders, one series for water and the other series for steam, pistons in said cylinders, the water-pistons connected with the steam-pistons and ducts controlled by said pistons, one steam-piston operating to control the movements of another and the movements of the water-piston connected with the latter.

3. A pumping-engine comprising two pairs of twin cylinders, each provided with inlet and outlet ports similarly constructed, pistons in said cylinders, said pistons having ducts therein communicating with the ducts of the cylinders, the ducts in all the pistons being similarly disposed, the ducts in the pistons of one pair arranged in reverse order in the ducts in the pistons of the other pair, and pistons-rod connecting the pistons of one pair with the pistons of the other pair.

4. In a pumping-engine, the combination with two cylinders provided with two pairs of ducts, one pair of said ducts connecting the center of one cylinder with the ends of the other cylinder, and the other pair of ducts connecting the center of the last-mentioned cylinder with the ends of the first-mentioned cylinder, of a piston in each cylinder, each piston having two ducts near one end arranged at right angles to each other and each terminating at diametrically opposite points on the piston, each piston also having near its other end, two reversely-curved ducts.

700,975. MIRROR ATTACHMENT FOR THEATER-CHAIR.
 HARRY A. HENDERSON, Brooklyn, N. Y. Filed Jan. 20, 1902. Serial No. 91,395. (No model.)

Claim.—An inseparable mirror attachment for theater-chairs and in combination with an arm pivotally mounted on the back of the chair to swing horizontally and having an annular groove at its other end, a coupling stem or tip having its lower end tubular and formed with integral shoulders or protuberances on its interior walls frictionally engaging or binding the groove of the arm to automatically maintain the adjustment of said stem, and a mirror-frame pivotally connected to the upper end of said coupling stem or tip, the pivot having its ends upset to produce friction whereby the adjustment of the glass is maintained and the stem and the mirror rendered inseparable from each other and from the arm.

700,976. PAPER-HANGER'S COLORING-TOOL. — BERNARD CLEM, Hartford, Conn. Filed July 31, 1901. Serial No. 79,396. (No model.)

Claim.—1. In a paper-hanger's coloring-tool, a box adapted to contain the coloring substance, said box being open at the top, a woven fabric adapted to close the box at the bottom, covers adapted to fit over the top and bottom of the box, a holder adapted to hold said box, means for securing said box within the holder, substantially as and for the purpose specified.

2. In a device of the character described, a box adapted to contain coloring substance, said box being open at the top, a woven fabric adapted to close the bottom of the box, two covers, one adapted to fit over the top of the box and the other over the bottom of the same, a holder adapted to hold the coloring-box, means for securing the box within the holder and removing the same therefrom, a handle formed with the holder, a cavity formed within the handle, and a cap adapted to close said cavity, substantially as described and for the purpose specified.

3. In combination with a device of the character described, a coloring-box consisting of the outside of the rectangular frame, an interior rectangular frame adapted to fit within the outside frame, both the inside and the outside frame open at the top and bottom, a woven fabric secured to the interior frame, two covers, one adapted to fit over the top of the box and the other over the bottom of the same, transverse ribs formed upon the ends of the box, grooves formed in the holder into which said ribs are adapted to slide, substantially as and for the purpose set forth.

4. In combination with a device of the character described, a holder consisting of a handle, a side strip secured to said handle and extending out therefrom, a cross-piece formed with said side strip upon the end of the same, a side strip pivoted to the cross-piece, means for securing the free end of said pivoted strip to the handle, said side strips, cross-piece and handle adapted to form a rectangular opening into which the coloring-box is adapted to be inserted, transverse grooves formed upon the inner face of the cross-piece and handle, ribs formed upon the end of the coloring-box adapted to fit within said grooves, a cavity formed within the handle, and a cap adapted to fit over the end of the handle, substantially as described and for the purpose set forth.

700,977. SUPPORT FOR PIANO. — ANDREAS GRAM, Ephraim, Utah. Filed Apr. 10, 1901. Serial No. 54,175. (No model.)

Claim.—1. A cushion for the leg or foot of a piano or other musical instrument consisting of a mass of soft elastically-yielding material having a concave under surface and a crown-plate of metal imposed on said mass, substantially as herein described.

2. A cushion for the support of the leg or foot of a piano or other musical instrument consisting of a mass of soft elastically-yielding material having a concave under surface and a crown-plate of metal having a

concave upper surface imposed on said mass, substantially as herein described.

700,978. HAMMOCK. — RALPH E. PALMER, Middletown, Conn. Filed Feb. 20, 1902. Serial No. 94,921. (No model.)

Claim.—1. A hammock having its body bifurcated at its opposite ends, substantially as set forth.

2. A hammock having its body bifurcated at its opposite ends and a gore inserted between the branches at the end of the hammock, substantially as set forth.

700,979. COMPOSITION OF MATTER FOR WELDING STEEL.
 CHARLES PARSONS, Kalamazoo, Mich. Filed Aug. 12, 1901. Serial No. 71,582. (No specimens.)

Claim.—1. Boracic acid combined with small particles of iron or steel for welding.

2. The combination of boracic acid, iron or steel, gelatin, and water, in the approximate proportions named above for a welding compound.

700,980. ELECTRIC SAWING-MACHINE. — CHARLES PARSONS, Newport, Ky., assignor to The Warr Frog Company, Cincinnati, Ohio, a Corporation. Filed Nov. 2, 1901. Serial No. 69,922. (No model.)

Claim.—1. In an electrical sawing-machine, a main motor-circuit, a cut-out switch, a controller in said circuit, a motor connected to a driving-shaft, a saw-shaft, in combination with a branch circuit connecting the main circuit between the controller and switch, said branch connection being provided with a switch and controller and in circuit with a feed-motor shaft geared to convey power to the feeding-sawings, substantially as specified.

2. In combination with a sawing-machine, a main power-circuit, a motor adapted to drive the saw-shaft, a controller in said circuit for regulating the power for the motor, a cut-out switch outside of the controller, a branch feed-motor circuit connecting with the main circuit between the switch and the controller, a feed-motor having its shaft connected by a train of belt gears to the feed-sawings, an electric controller in said branch circuit, whereby said switch is adapted to simultaneously cut out both motors, substantially as herein described.

3. In combination with a sewing-machine consisting essentially of a main circuit, a motor-controller, a switch, a branch circuit having connection with the main circuit between said main switch and power-motor controller, a branch switch and feed-motor controller, a motor located in said branch circuit, a feed-carrage connected by a train of belt gears to the shaft of said motor in said branch circuit, device for storing up power with a forward movement of said carrage, means for unshipping the geared connection between said carrage and its motor-shaft, whereby the feed-carrage is automatically retracted independent of all the power driving device and of the energy transmitted by said circuit, substantially as described.

4. In machine-working machine employing a cutting-tool, a carrage for supporting and feeding the work to the tool, the combination thereof of a main electric circuit, a motor and controller for driving the cutting-tool, a switch for cutting in said main circuit, a branch circuit connected with the main circuit between the motor and switch, a controller and an electric motor in said branch circuit, said branch-circuit motor being geared to the feed-carrage whereby the feed may be regulated or the branch circuit may be cut out independent of the main circuit and both circuits simultaneously may be controlled by a single switch, substantially as described.

5. In combination with an electrical sewing-machine, a feed-motor located upon the frame of the machine having a geared connection with a feeding-carrage, a power-motor independent of said machine with device for transmitting motion to the aw-shaft, a main circuit in which said power-motor is located, a controller and a switch in said main circuit, a branch circuit connecting with the main circuit between the switch and controller thereof and in circuit connection with the feed-motor, a switch and controller in said branch circuit, substantially as described.

700,981. VARIABLE-SPEED CHARKING. SHAW DE FRANK, St. Maurice, France, assignor to SA de Frang, H. Collier Lonsard et Co., St. Maurice, France. Filed July 26, 1901. Serial No. 60,125. (No model.)

Claim.—1. In a gearing, the combination of a pair of toothed gears adapted to be moved relatively to each other in an axial direction for engagement or disengagement, said gears being normally out of engagement, and means for pressing said gears yieldingly toward each other to bring them into engagement.

2. In a variable-speed gearing, the combination of a driving-shaft,

pinions carried thereby, a driven shaft, corresponding gears carried thereby and adapted to engage with said pinions to produce different speeds of the driven shaft, springs tending to bring said pinions into engagement with their corresponding gears, and means for releasing each of said springs in succession to bring its pinion into engagement with its corresponding gear.

3. In a variable-speed gearing, the combination of a series of springs 13, sliding blocks 20, levers 12 and 14 engaging said sliding blocks, and means for operating said levers 12 and 14 to disengage one of said springs and permit the others to operate.

4. In a variable-speed gearing, the combination of a driving-shaft, pinions carried thereby, a driven shaft, gears carried thereby, springs tending to bring said pinions into engagement with their corresponding gears, a common shaft, and cams carried thereby and adapted as said shaft is rotated continuously in one direction to bring the pinions successively into and out of engagement with their corresponding gears.

700,982. DRAW-BAR ATTACHMENT FOR LOCOMOTIVES. WILLIAM F. RICHARDS, Buffalo, N. Y., assignor to Gould Coupler Company, New York, N. Y., a Corporation of West Virginia. Filed Nov. 21, 1901. Serial No. 52,173. (No model.)

Claim.—1. The combination with a locomotive-pilot, of a guide-bar supported by said pilot, a draw-bar mounted to move laterally and having its forward end guided by said bar, spring-pockets slidably mounted on said bar, oppositely-arranged springs carried by said pockets, a stop between said pockets, and a rod or bar connected at its opposite ends to the outer ends of said springs and movable relative to said spring-pockets substantially as set forth.

2. The combination with a locomotive-pilot, and a draw-bar mounted to swing laterally, of a guide and supporting box for the forward end of said draw-bar attached to said pilot, guides on said box, oppositely-arranged spring-pockets slidably mounted in said guides, an abutment or stop between said spring-pockets, oppositely-arranged coiled springs seated in sockets in the outer sides of said spring-pockets, a rod or bar passing through said coiled springs and through openings in said spring-pockets, and stops or abutments at the opposite ends of said rod or bar engaging the outer ends of said coiled springs, substantially as set forth.

3. The combination with a locomotive-pilot and a draw-bar mounted to swing laterally, of a guide and supporting box secured to said pilot and having oppositely disposed guides and a centrally-disposed depending post or standard secured to the pilot, spring-pockets slidably mounted in said guides and having upwardly-projecting abutments arranged on opposite sides of said draw-bar and in their outer sides with sockets, a stop or abutment on said depending post between said spring-pockets, oppositely-arranged coiled springs having their inner ends seated in said sockets, and a rod or bar passing through openings in said spring-pockets and through said coiled springs, and stops or abutments at the opposite ends of said rod or bar engaging the outer ends of said coiled springs, substantially as set forth.

4. The combination with a locomotive-pilot, and a draw-bar mounted thereon to move laterally, of a guide-box for said draw-bar having a depending post, plates or bars rising from the lower part of said pilot to which said post is secured, a substantially U-shaped bracket arranged in rear of said guide-box and secured at its upper end to the upper part of said pilot and at its lower end to said plates or bars, said draw-bar passing between the arms of said bracket and through said guide-box, substantially as set forth.

700,983. GUN-CARTRIDGE. WILLIAM H. BURGESS, Monticello, Tenn. Filed Sept. 20, 1901. Serial No. 51,509. (No model.)

Claim.—A cartridge comprising a tapering shell and contracted at its forward end, a tapering plug fitted into the rear end of the shell and

having the tapering opening adapted to receive the cap, the forward faces of said plug being concave and a projectile convex at both ends and fitting into the contracted end of the shell, the inner end of said projectile having a recess produced therein, and a wad arranged in contact with the rear end of the projectile, said wad having its front and rear faces concave and the explosive adapted to be contained in the shell between the concave face of the plug and wad, said wad being secured at the juncture of the main portion of the shell and the contracted forward end, substantially as described.

700,984. MEASURING-CAN. WILLIAM E. BROWN, Grafton, N. Y. Filed Sept. 20, 1901. Serial No. 70,984. (No model.)

Claim.—1. A can provided with measuring-compartments arranged one directly over the other, a discharge-spout attached to the bottom of the lower compartment, ports in the tops of the compartments and disposed in range with said discharge-spout, a stem passing vertically through said ports and to the discharge-spout, and valves attached to said stem and controlling the discharges through said ports and spout as set forth and shown.

2. A can provided with measuring-compartments arranged one above the other inside of the can and each of said compartments provided with an opening in its top, removable covers closing said openings, means for retaining the covers in their closed positions, a discharge-spout attached to the lowermost compartment, discharge-ports in the tops of the compartments, valves controlling the discharges through said ports and spout, and a stem carrying said valves to move them simultaneously as set forth.

3. A can provided with measuring-compartments arranged one above the other inside of the can and each of said compartments provided with an opening in its top, removable covers closing said openings, means for retaining the uppermost cover in its closed position, a prop interposed between said cover and adjacent cover to confine the latter in its closed position, a discharge-spout attached to the lowermost compartment, discharge-ports in the tops of the compartments, valves controlling the discharges through said ports and spout, and a stem carrying said valves to move them simultaneously as set forth.

4. A can provided with measuring-compartments arranged one above the other, a discharge-spout attached to the lowermost compartment, discharge-ports in the tops of said compartments, a stem passing through said ports, and valves attached to said stem and spaced to open the spout and close the ports in succession by the upward movement of the stem as set forth.

5. A can provided with measuring-compartments arranged one above the other, separate ventiducts extending from the tops of the compartments and disposed telescopically one within the other, a discharge-spout attached to the lowermost compartment, discharge-ports in the tops of the compartments, a stem passing through said ports, and valves attached to said stem and spaced to open the spout and close the ports in succession by the upward movement of the stem as set forth.

6. A can provided with measuring-compartments arranged one above the other, a discharge-spout attached to the lowermost compartment, discharge-ports in the tops of the compartments, a stem passing through said ports, valves attached to said stem and spaced to open the spout and close the ports in succession by the upward movement of the stem, and gages on the stem and can determining the positions of the valves as set forth.

7. A can provided with measuring-compartments disposed one above the other and each of said compartments provided with an opening in its top, removable covers closing said openings, discharge-ports in said covers, a discharge-spout attached to the lowermost compartment, guides determining the movement of the covers, a stem passing through said ports,

valves attached to said stem and spaced to open the spout and close the ports in succession, and gages on the stem and can determining the positions of the valves as set forth.

8. A can provided with measuring-compartments disposed one above the other and each of said compartments provided with an opening in its top, removable covers closing said openings, separate ventiducts extending from said covers and disposed telescopically one within the other, a discharge-spout attached to the lowermost compartment, discharge-ports in the lowermost cover, a stem passing through said ports, valves attached to said stem and spaced to open the spout and close the ports in succession by the upward movement of the stem, and gages determining the positions of the valves as set forth.

9. A can provided with measuring-compartments disposed one above the other, a discharge-spout attached to the lowermost compartment, discharge-ports in the tops of the compartments, a stem passing through said ports, a valve attached to the lower end of said stem for controlling the discharge through the spout, a spring forcing the stem downward to automatically close the spout, valves attached to the stem and spaced to open the discharge-ports in succession by the upward movement of the stem, and gages on the stem and can to determine the positions of the valves as set forth.

10. A can provided with measuring-compartments disposed one above the other inside of the can and each of said compartments provided with an opening in its top, removable covers closing said openings, ventiducts extending from said covers and arranged telescopically one within the other, means for retaining the cover of the uppermost compartment in its closed position, a prop interposed between the covers, a discharge-spout attached to the lowermost compartment, discharge-ports in the lowermost cover, guides determining the positions of the closed covers, a stem passing through the discharge-ports, a valve attached to the lower end of the stem to control the discharge through the spout, valves attached to said stem and spaced to open the discharge-ports in succession by the upward movement of the stem, a spring forcing the stem downward to automatically close the spout, and gages on the stem and can determining the positions of the valves as set forth and shown.

700,985. BALANCE VALVE. EDWIN E. BROWN, Rochester, N. Y. Filed July 20, 1904. Serial No. 26,187. (No Model.)

Claim.—1. In a balance valve, a cylinder having inlet and exhaust ports, a slide-valve for causing inlet and exhaust of steam to the ends of the cylinder, a steam-chest, a box secured to the back of slide-valve and a movable metallic packing supported on a base on said box and fitting the exterior of said box and against the steam-chest cover and having one or more grooves on its surfaces in contact with said box and said base and open passages from said grooves to the interior only of said box, substantially as described.

2. In a balance valve, a cylinder having inlet and exhaust ports, a slide-valve for causing inlet and exhaust of steam to the ends of the cylinder, a steam-chest, a box secured to the back of the slide-valve, and a movable metallic packing supported in a base on said box and fitting the exterior of said box and against the steam-chest cover and having one or more grooves on its surfaces in contact with said box, said base and said steam-chest cover, and open passages from said grooves to the interior only of said box, substantially as described.

3. In a balance valve, a cylinder having inlet and exhaust ports, a slide-valve for causing inlet and exhaust of steam to the ends of the cylinder, a steam-chest, a box secured to the back of the slide-valve, and a movable metallic packing supported on a base on said box and fitting steam-tight against the outer surface of the box and against the under surface of the steam-chest cover and upon said base, means for pressing said base upward against the steam-chest cover, said packing having grooves on the surfaces pressing against said box and said base, and open connections from said grooves to the interior only of the box, substantially as described.

4. In a balance valve, a cylinder having inlet and exhaust ports, a slide-valve for causing inlet and exhaust of steam to the ends of the cylinder, a steam-chest, a box secured to the back of the slide-valve, and a movable metallic packing supported on a base on said box and fitting steam-tight against the outer surface of the box and against the under surface of the steam-chest cover and upon said base, means for pressing said base upward against the steam-chest cover, said packing having

grooves on the surfaces pressing against the steam-chest cover, said box and said base, and open connections from said grooves to the interior only of the box, substantially as described.

700,986. RUBBER TUB. GEORGE D. SMITH, Buffalo, N. Y.
Filed May 14, 1901. Serial No. 60,366. (No model.)

Claim.—1. In an instrument of the character described, the combination of a tubular body having an enlarged air-reservoir, provided with an opening, and a contracted outlet end, and a diaphragm over said opening, substantially as set forth.

2. In an instrument of the character described, the combination of a tubular body having a substantially elliptical mouth portion, an enlarged air-reservoir, and a contracted outlet end, and a diaphragm over an opening in said air-reservoir, substantially as set forth.

3. In an instrument of the character described, the combination of a tubular body having a substantially elliptical mouth portion, an enlarged air-reservoir, and a tapering rear portion provided at its end with an inwardly-extending flange surrounding an outlet-opening, and a diaphragm over an opening in the air-reservoir, substantially as set forth.

4. In an instrument of the character described, the combination of a tubular body portion provided with an opening and having a through-passage which is enlarged adjacent to said opening to form an air-reservoir and is contracted at its outlet end, a diaphragm over said opening, and a trumpet-shaped device surrounding said diaphragm, substantially as set forth.

5. The combination of a tubular body having an opening, of a diaphragm covering said opening, a ring to which said diaphragm is secured, and means for bending said ring to tension the diaphragm and for clamping the ring in place, substantially as set forth.

6. The combination with a tubular body having an opening surrounded by an inclined flange, of a diaphragm, a ring to which the same is secured and which rests on said inclined flange, and a trumpet having a screw-threaded engagement with a part carried by the body and acting to bend said ring on said inclined flange to tension the diaphragm, substantially as set forth.

7. The combination of a metallic tubular body having an opening intermediate of its ends, an inclined flange surrounding said opening, a screw-threaded ring secured to said flange, a diaphragm, a diaphragm-ring to which the diaphragm is secured and which bears at its outer edge on said inclined flange, and a trumpet secured into said screw-threaded ring and having a flange which bears on said diaphragm-ring at or near its inner edge, substantially as set forth.

700,987. HARVESTER-BELT. JAMES S. SEWELL, Bath, Ohio.
Filed Oct. 11, 1901. Serial No. 73,315. (No model.)

Claim.—1. An improved conveyor-belt for harvesters having external cross-ribs to convey the cut grain and racks of short transverse ridges less in length than the width of said belt on the inside to engage corrugations on the driving-roller, substantially as shown and described.

2. The combination with a conveyor-belt for harvesters having external cross-ribs and racks of short transverse ridges less in length than the width of said belt on the inside, of a driving-roller having lines of short corrugations to engage said ridges, substantially as shown and described.

3. An improved conveyor-belt having joining-ribs on one end situated back from the end and buckles on the other end, one whereof is at the end of the belt and the others back therefrom, with openings in said belt adjacent to said latter buckles to permit said straps to pass through from the inside to the buckles, substantially as shown and described.

700,988. METALLIC PACKING. DAVID F. SEATMAN, Baltimore, Md.
Filed Nov. 12, 1900. Serial No. 34,302. (No model.)

Claim.—1. The combination with a stuffing-box and a piston rod or shaft, of a plurality of contacting packing-rings, movable concentrically therein, independently of each other, each packing-ring comprising a series of radially-movable separable segments having radial meeting ends,

springs to press said segments inwardly, on radial lines and maintain said segments in contact with said piston rod or shaft, whereby said packing-rings are adapted to move concentrically in said stuffing-box to conform to any eccentricity or crookedness in the piston rod or shaft on which the packing-rings bear, and whereby each segment of each packing-ring is movable radially, independently of its fellows, to compensate for variations in the surface of the piston rod or shaft, the joints between the segments of said respective packing-rings being out of line with each other, substantially as described.

2. The combination with a stuffing-box and a piston rod or shaft, of a plurality of contacting packing-rings, movable concentrically therein, independently of each other, each packing-ring comprising a series of radially-movable separable segments having radial ends, springs to press said segments inwardly, on radial lines and maintain said segments in contact with said piston rod or shaft, whereby said packing-rings are adapted to move concentrically in said stuffing-box, to conform to any eccentricity or crookedness in the piston rod or shaft on which the packing-rings bear, and whereby each segment of each packing-ring is movable radially independently of its fellows, to compensate for variations in the surface of the piston rod or shaft, the joints between the segments of said respective packing-rings being out of line with each other, one segment of one packing-ring having a dovetail-pin projecting from one side thereof, and one segment of the other packing-ring having an opening to receive said dovetail-pin, said opening admitting of lost motion of said dovetail-pin therein, substantially as described.

3. The combination with a stuffing-box, of a plurality of contacting packing-rings movable concentrically therein, independently of each other, each packing-ring comprising a series of segments having radial ends, and flat springs bearing inward on said segments and said springs having offsets and said segments having notches in their outer edges engaged by said offsets, whereby the said packing-rings conform to any eccentricity or deviation from a straight line in the piston rod or shaft on which the packing-rings bear, and each segment of each packing-ring being movable radially, independently of its fellows, to compensate for variations in the surface of the piston rod or shaft, one segment of one packing-ring having a dovetail-pin, and the opposing segment of the adjacent packing-ring having an opening engaged by said dovetail-pin, said pin having lost motion in said opening, substantially as described.

700,989. AUTOMATIC FUSE-SWITCH FOR TELEGRAPH OR OTHER CIRCUITS. CLARENCE A. STANTON, Philadelphia, Pa.
Filed Aug. 20, 1901. Serial No. 73,548. (No model.)

Claim.—1. In an automatic lightning-arrester or fuse-switch, the combination of a branching main conductor, a separate fuse connected to each of the branches of the conductor and arranged at widely-separated points, a contact fixedly supported and holding the free end of one of the fuses whereby it is supported at both ends, a second main conductor, a spring-actuated movable contact-arm having a support connected with said second main conductor and located intermediate of the last-mentioned or fixed contact and the terminal of the other fuse and having its free end directed laterally away from the fixed contact and secured to the free end of the last-mentioned fuse to hold it taut with its length directed laterally away from the other fuse and so that said arm is held normally out of contact with the fixed contact of the other fuse whereby the arm moves laterally away from the normal direction of the length of the fuse holding it when said fuse is ruptured and makes contact with the fixed contact of the other fuse.

2. In an automatic lightning-arrester or fuse-switch, the combination

of a spring-actuated pivoted contact-arm E, a fine-clamp F near one end of the pivoted end of the contact-arm E, a fine G between said clamp and the free end of the contact-arm E so that the arm makes an acute angle with the fine, a contact J upon the opposite side of the pivoted end of the contact-arm and adapted to receive B when released from the fine G, a fine M connecting with the contact J, and two terminals of a divided circuit one connecting with the pivoted contact-arm E and the other connecting with both the clamp F and the fine M substantially as set forth.

5. In an automatic lightning-arrester or fine-switch, the combination of a shape of insulating material, two terminal binding-posts secured thereon, two fine-clamps electrically connected with one of said binding-posts, a spring-actuated pivoted contact-arm also carried by the base and between the fine-clamps, an electric circuit between the contact-arm and the other of the terminal binding-posts, a fine-clamp carried upon the free end of the contact-arm, a fine between one of the fine-mentioned fine-clamps and the fine-clamp on the contact-arm making an acute angle with the length of the contact-arm, a contact for the contact-arm arranged on the base upon the opposite side of the arm relatively to the above-mentioned fine, a fine-clamp electrically connected with the contact-arm, and a fine between the last-mentioned fine-clamp and the other of the first-mentioned fine-clamps.

700,990. LIQUID-COOLING APPARATUS. EVA R. BROOKER, St. Louis, Mo., assignor to John Brocker, deceased. Filed July 21, 1899. Serial No. 725,094. (No model.)

Claim.—In a liquid-cooling apparatus, the combination of a tower containing checker-work partitions, liquid-distributing troughs arranged at the upper end of said tower and provided with outlets to permit the flow of liquid therefrom onto said partitions, delivery-troughs arranged transversely of said distributing-troughs and provided with apertures arranged to deliver liquid into said distributing-troughs, said apertures open on one side thereof to prevent clogging of the same, and liquid-receiving troughs arranged transversely of said delivery-troughs and provided with outlets adapted to discharge into said delivery-troughs.

700,991. MICA CHIMNEY. ALBERT F. STUBBS, Oswego, N. Y., assignor to Sturtevant Company, Oswego, N. Y., a Corporation of New York. Filed Jan. 16, 1900. Serial No. 1,000. (No model.)

Claim.—As a new article of manufacture, a mica chimney comprising a series of vertical ribs S-shaped in cross-section, a series of ribs parallel to the ribs formed by said ribs, a head 4 at the bottom

end of the chimney having an upward flange 5 which engages the lower end of said ribs, a head 6 at the top of the ribs, said head being bent over upon the ribs, a plurality of legs or tongues 10 carried by the ribs and located within the upper head, and a metallic tapering upper portion for the chimney provided with a cylindrical lower part and coated within the mica chimney with a head 8 resting on the head 6 and having openings through which said legs or tongues are passed laterally, substantially as and for the purposes set forth.

700,992. BOLTLISS EAST-STEEL CAR-TRUCK. WM. B. STUBBS, Savannah, Ga. Filed July 6, 1901. Serial No. 67,303. (No model.)

Claim.—1. In a boltliss east-steel car-truck frame, the combination with the side frames each cut in a single piece and having a central transverse opening, of a transom having its ends fitted in said openings and hinged to the side frames, said transom being provided with rigid spring-cuts disposed at opposite sides of the longitudinal center of the side frames.

2. In a boltliss east-steel car-truck frame, the combination with the side frames, each cut in a single piece and having a central transverse opening, of a transom having its ends fitted into said openings and hinged to the side frames, said transom being provided with rigid spring-cuts disposed substantially in the plane of the bottom of the transom and at opposite sides of the longitudinal center of the side frames.

3. In a boltliss east-steel car-truck frame, the combination with the side frames, each cut in a single piece and having a central transverse opening, of a transom having its ends fitted in said openings and hinged to the side frames, said transom comprising side members and intermediate integral spring-cuts disposed substantially in the plane of the bottom edges of the side members and at opposite sides of the longitudinal center of the side frames.

4. In a boltliss east-steel car-truck frame, the combination with the side frames, each cut in a single piece and provided respectively with central transverse openings, of a transom formed in a single piece and having its ends fitted into said openings and hinged to the side frames, said transom having integral spring-cuts disposed at opposite sides of the side frames, and a truck-bolter having its ends extended into the openings on the side frames and provided with spring-cuts coincident with the spring-cuts of the transom.

5. In a boltliss east-steel car-truck, the combination with side frames, each cut in a single piece and provided respectively with central transverse openings, of a transom formed in a single piece and having its ends fitted into said openings and hinged to the side frames, said transom having integral spring-cuts disposed substantially in the plane of the bottom of the transom and located at opposite sides of the side frames, and a truck-bolter having its ends extended into the openings in the side frames and provided with spring-cuts disposed in a plane above the bottom of the bolter and coincident with the spring-cuts of the transom.

6. In a boltliss east-steel car-truck, the combination with the side frames each cut in a single piece, and provided respectively with central transverse openings, of a transom formed in a single piece and having its ends fitted in said openings and hinged to the frame, said transom having integral spring-cuts disposed substantially in the plane of the bottom of the transom and located at opposite sides of the side frames, and a truck-bolter having its ends extended into the openings in the side frames and provided with spring-cuts disposed in a plane above the bottom of the bolter and coincident with the spring-cuts of the transom.

7. In a boltliss east-steel car-truck, the combination with the side frames provided with central transverse openings, and a transom having its ends extended into said openings and hinged to the side frames, of a bolter having the form of a hollow casting and provided at its opposite ends with transverse diaphragms disposed in a plane between the top and bottom of the bolter and within the hollow casting, said diaphragms constituting spring-cuts disposed at opposite sides of the longitudinal center of the side frames.

8. In a boltliss east-steel car-truck, the combination with the side frames, each cut in a single piece and provided with a central transverse opening, of a transom having its ends extended into said openings and hinged to the side frames, said transom being provided with rigid spring-cuts disposed substantially in the plane of the bottom of the transom and at opposite sides of the longitudinal center of the side frames, said transom being also formed with terminal supports integral with the spring-cuts and spaced below the same.

9. In a boltliss east-steel car-truck, the combination with side frames, each cut in a single piece, and provided with a central transverse opening having its ends extended out to define a series of separated bearing-plates, of a transom having its ends fitted into said openings and hinged to the side frames, said transom being provided with separated bearing-plates disposed opposite the bearing-plates of the side frames.

10. In a boltliss east-steel car-truck, the combination with the side frames, each cut in a single piece and provided with a central transverse opening, the walls of the opening being curved out at the corners thereof and at intermediate points to define separated bearing-plates, of a transom having its ends extended into the openings in the side frames and provided with bearing-plates disposed opposite the bearing-plates of the side frames, said side frames and transom being hinged together.

11. In a boltliss east-steel car-truck, the combination with the side frames having central transverse openings, of a transom having open ends fitted into said transverse openings, the contacting faces of the transom and side frames having vertically-extending key-cuts, the key-cuts in the side frames being curved out intermediate of their ends, and keys fitted in said coinciding key-cuts.

12. In a boltliss east-steel car-truck, the combination with the side frames having a central transverse opening, of a transom having its ends extended into said openings, the adjacent surfaces of the side frames and transom each having spaced bearing-plates, and coincident key-cuts formed in the side frames and transom, the key-cuts in the side frames being curved out opposite the spaces between the adjacent bearing-plates.

13. In a boltliss east-steel car-truck, the combination with the side frames, each cut in a single piece and provided respectively with central transverse openings, and flat bearing-plates above said openings, of a transom having its ends extended into the openings and hinged to the side frames, a truck-bolter having its ends extended through the openings in the side frames and provided with thrust-flanges disposed to bear against the flat bearing-plates of the side frames, and springs interposed between the truck bolter and frame, said springs being located at opposite sides of the side frames.

14. In a boltliss east-steel car-truck, the combination with the side frames, each cut in a single piece and provided with a central transverse opening, of a transom having its ends extended into said openings and hinged to the side frames, said transom being provided with rigid spring-cuts disposed substantially in the plane of the bottom of the transom and at opposite sides of the longitudinal center of the side frames, said transom being also formed with terminal supports integral with the spring-cuts and spaced below the same, and with tie-bars extending between the sides of the transom in vertical alignment with the terminal supports in immediate bearing-plate contact against the upper edges of the openings in the side frames.

15. In a boltliss east-steel car-truck, the combination with the side frames, each cut in a single piece and provided respectively with central transverse openings and flat bearing-plates above said openings, of a transom having its ends extended into the openings and hinged to the side frames, said transom being provided with transverse tie-bars located in the plane of the side frames and disposed to bear against the upper walls of the transverse openings, a truck-bolter having its ends extended through the openings in the side frames and provided with thrust-flanges disposed to bear against the flat bearing-plates of the side frames and against the tie-bars of the transom, and springs interposed between the truck and bolter frame, said springs being located at opposite sides of the side frames.

16. In a boltliss east-steel car-truck frame, the combination with the side frames, each cut in a single piece and provided respectively with central transverse openings, of a transom formed in a single piece and having its ends fitted into said openings and extended beyond the side frames, said transom having integral spring-cuts disposed at opposite sides of the side frames, and a truck-bolter located within the transom and having its ends extended through the openings in the side frames, said truck-bolter being longitudinally coextensive with the transom and provided with spring-cuts coincident with the spring-cuts of the transom.

17. An car-truck comprising a combined upper member, a lower member having its ends substantially parallel and integral with the upper member, integral posts connecting the middle portions of the upper and lower members; and a spring-cut supported between said posts.

18. An car-truck comprising a combined upper member, a lower member having its ends substantially parallel and integral with the upper member, integral posts connecting the middle portions of the upper and lower members; and a spring-cut supported between said posts, the opposite faces of the posts and the contiguous faces of the upper and lower members being formed with spaced bearing-plates.

19. An car-truck comprising a combined upper member, a lower member having its ends substantially parallel and integral with the upper member, integral posts connecting the middle portions of the upper and lower members; and a spring-cut supported between said posts, the opposite faces of the posts and the contiguous faces of the upper and lower members being formed with spaced bearing-plates.

20. A transom comprising side members, and integral spring-cuts intermediate of the side members and extended beyond the ends thereof.

21. A transom comprising parallel side members, integral spring-cuts intermediate of the side members and extended beyond the ends thereof, and integral supports located below the spring-cuts.

22. A bolter having the form of a hollow casting and comprising substantially parallel side walls, a combined top wall, and integral spring-cuts extended between the side walls of the bolter at the opposite ends thereof and at points above the bottom of the bolter.

23. A bolter having the form of a hollow casting and comprising substantially parallel side walls, a combined top wall, the ends of which are disposed horizontally, and integral spring-cuts extending between the side walls substantially midway between the bottom of the bolter and the horizontal ends of the top wall.

700,998. EXPANDIBLE FISH-BOCK. ARTHUR TAYLOR, Boston, Mass. Filed Jan. 29, 1902. Serial No. 91,770. (No model.)

Claim.—1. An expandible fish-bock comprising a stem, an elastic head adapted to move along the stem, an expander on the stem to move within the head, and hooks held by the head and controlled by the expander, substantially as shown and described.

2. An expandible fish-bock comprising a stem, an elastic head adapted to move along the stem, an expander on the stem to move within the head, having peripheral loops or guides, and hooks held by the head and occupying the loops, substantially as set forth.

3. An expandible fish-bock comprising a central stem, a hollow elastic head adapted to move along the stem, the latter having an enlarged part to enter the head to form a frictional tension with the same, a series of hooks carried by the head, and an expander rigid with the stem to control the hooks, substantially as shown and described.

4. A multiple fish-bock comprising a stem having an enlarged part, a hollow elastic head divided at one end adapted to receive the enlarged part of the stem, a series of hooks held by the head, and an expander to control the hooks, substantially as shown and described.

5. An expandible fish-bock comprising a stem, an elastic head adapted to move along the stem, a bulged or curving expander on the stem the bulge of which is engaged by said head, said expander being formed with inclined radial loops equally spaced at its edge, and a series of hooks held by the head and occupying the respective loops, the hooks bearing against the expander, substantially as shown and described.

6. An expandible fish-bock comprising a stem, an elastic head adapted to move along the stem, an expander on the stem adapted to expand said head, and hooks held by the head and controlled by the expander, there being a yielding friction-bearing of the head against the stem, substantially as and for the purposes specified.

7. An expandible fish-bock comprising a stem, an elastic head adapted to move along the stem, an expander on the stem, and hooks held by the head and controlled by the expander, means being provided within the head to cause the stem and the head to act both independently, and together as one piece, substantially as and for the purposes specified.

700,994. ALKYLING, SMOULING, AND BOWLING OF RAIL ENDS. FRANK D. TOWN and DANIEL R. BAKER, Baltimore, Md. Filed Feb. 18, 1901. Renewed Feb. 24, 1901. Serial No. 72,577. (No model.)

Claim.—1. The herein-described improvement in the art of joining adjacent ends of railroad-rails, consisting in applying cheeks thereto which are preliminarily heated in a welding heat and finally applying sufficient continued pressure to the outer opposite faces of the cheeks to weld the same together and simultaneously raise the heads of the rails into correct alignment; substantially as described.

2. The herein-described improvement in the art of joining the adjacent ends of railroad-rails consisting in applying cheeks thereto which are preliminarily heated to a welding heat, applying sufficient continued pressure to the outer opposite faces of the cheeks to weld said cheeks together and raise the head of the rail into correct alignment and restraining the vertical spreading of said rail ends at the point of surface alignment; substantially as described.

3. The herein-described improvement in the art of joining adjacent ends of railroad-rails consisting in applying a rigid mold to the rail-ends, applying cheeks which are preliminarily heated to a welding heat

to the opposite faces of the rail ends and finally applying sufficient continued pressure to the opposite faces of the cheeks to weld said cheeks together and spread the rail ends into contact with the web; substantially as described.

4. The herein-described method of joining adjacent ends of railroad rails consisting in perforating the webs of the rails near their ends, applying cheeks thereto which are preliminarily heated to a welding heat, applying sufficient continued pressure to the outer opposite faces of the cheeks to weld the rail ends together through the perforations in the webs and spread said rail ends vertically and restraining the spreading action of said rail ends to form a true wheel-rim; substantially as described.

5. The alignment of rail ends, consisting in placing the adjacent rail ends in a top and bottom clamp shaped to the required alignment, and forcing them into said clamp by pressure laterally applied to the said rail ends between the top and bottom of the clamp.

6. The alignment of rail ends, consisting in placing the adjacent rail ends in a top and bottom clamp shaped to the required alignment, heating said rail ends, and forcing them into said clamp, by pressure applied to said ends between the top and bottom of the clamp.

7. The alignment of rail ends and the securing of the same, consisting in placing the adjacent rail ends in a clamp shaped to the required alignment, securing metal plates against said rail ends thereto, and forcing said rail ends into said clamp.

8. The alignment of rail ends having apertures therein and the securing of the same together, consisting in placing the adjacent rail ends in a clamp shaped to the required alignment, welding heated metal cheeks placed against said rail ends together through said apertures by pressure applied thereto and heating said rail ends by heat from the said heated metal cheeks and the pressure applied thereto, and forcing said heated rail ends into said clamp by pressure laterally applied.

9. The alignment of rail ends having apertures therein and the securing of the same together, consisting in placing the adjacent rail ends in a clamp shaped to the required alignment, welding heated metal cheeks placed against said rail ends together through said apertures by pressure applied thereto and heating said rail ends by heat from the said heated metal cheeks and the pressure applied thereto, and forcing said heated rail ends into said clamp by pressure laterally applied.

10. The herein-described mode or method of joining adjacent ends of railroad rails consisting in applying heated cheeks thereto, and finally applying sufficient pressure to the outside surfaces of said cheeks to cause them to adhere to said rails, and to spread the ends thereof vertically, substantially as described.

700,995. AIR-FORGING DEVICE FOR ATOMIZING. CHARLES J. WALK, New York, N. Y., assignor to West Manufacturing Company, New York, N. Y., a Corporation of New York. Filed Mar. 20, 1901. Serial No. 51,503. (No model.)

Claim.—1. In an air-forging device for atomizing, the combination with a door and its frame, of a swinging arm hinged to the frame, a cylinder and its piston, the cylinder-piston being pivoted to the door and the cylinder being pivoted to the swinging arm, substantially as set forth.

2. In an air-forging device for atomizing, the combination with a door and its frame, of a swinging arm hinged to the frame, a cylinder

and its piston, the cylinder-piston being pivoted to the door and the said cylinder being at its opposite ends pivoted to and supported by the swinging arm, substantially as set forth.

3. In an air-forging device for atomizing, the combination with a door and its frame, of a spring-actuated swinging arm normally in engagement with the frame, a cylinder and its piston, the cylinder-piston being pivoted to the door, the said cylinder being at its opposite ends pivoted to and supported by the spring-actuated arm, substantially as set forth.

4. In an air-forging device for atomizing, the combination with a door and its frame, a bracket secured to the door, a swinging arm hinged to the door-frame, a cylinder and its piston, the cylinder-piston being hinged to said bracket, the said cylinder being pivoted to and supported by the swinging arm at its outer end, substantially as set forth.

700,996. SHIPPING CRATE. WILLIAM S. WILLIAMS, Clark Mills, N. Y. Filed May 25, 1900. Serial No. 17,951. (No model.)

Claim.—1. In a shipping-crate, vertically-slatted walls, upper and lower frame-bars, grooved in the direction of their length for receiving and holding the upper and lower ends of the slatted walls, a dotted bottom, and pieces slotted in the direction of their length for receiving and supporting the opposing ends of the bottom, grooves in the inner vertical faces of the upper frame-section, a slotted cover, a pivoted locking device pivoted to the cover and adapted to swing into engagement with the grooves in the vertical faces of the upper section of the frame, combined substantially as set forth, for the purpose stated.

2. In a shipping-crate, the combination of vertically-slatted walls or sides, bottom and top frame-sections both being in the form of the open molding and each provided with a groove in the direction of its length to receive and support the walls of the shipping-crate, slotted top and bottom, the grooved and pieces for supporting the ends of the top and bottom sections of the crate, oppositely-disposed grooves in the inner upper faces of the top frame-section, a pivoted locking device pivoted to the lid and constructed to swing into and out of engagement with the grooves for locking and unlocking the cover, combined substantially as set forth for the purpose stated.

3. A shipping-crate comprising the corresponding top and bottom rigid frames, vertical flexible side walls forming the covering connections between said top and bottom frames, each frame formed of bars rigidly secured together at their ends, the bottom frame-bars transversely beveled or inclined outwardly and downwardly at their inner edges and the top frame-bars correspondingly beveled at their outer edges so that the crates can be nested one on the other as described, a bottom secured in the bottom frame and comprising opposite side bars at the inner edges of and secured to the bottom frame-bars and flexible material extending and clasp its opposite edges secured to said side bars, said side walls at their upper and lower edges secured to and longitudinally of the frame-bars and having vertically-slanted openings, as described.

4. A shipping-crate comprising the rectangular corresponding top and bottom frames formed of open molding-bars so that the crates can be nested one on the other, the top frame having the lower angular corners 51, a bottom secured in the bottom frame, said frame grooved

throughout the lengths of their bars, and the flexible vertical walls formed of veneer sheets connecting said frames and secured throughout the lengths of their upper and lower edges in said grooves, said vertical walls formed with the vertical slots as described.

5. A shipping-crate comprising vertical walls, a rectangular bottom frame secured to said walls and consisting of bars secured rigidly together, and a bottom secured within said bottom frame and comprising side bars at and fitting the inner edges of opposite frame-bars and an elastic wall at its edges secured to the longitudinal edges of said side bars and formed with openings throughout, substantially as described.

6. A rectangular shipping-crate comprising a bottom and vertical walls all secured together, each wall composed of a panel consisting of two longitudinal bars having their opposite edges longitudinally grooved and one or more sheets of veneer between and connecting said bars and at its opposite edges fitted and secured in said grooves, substantially as described.

7. A rectangular shipping-crate comprising the vertical walls and a bottom all secured together, a cover, each of said elements formed by a panel having transverse openings and composed of edge bars longitudinally grooved at their opposite edges and one or more sheets of veneer extending between and connecting said bars and at its edges fitted and secured in said grooves, substantially as described.

8. A rectangular shipping-crate comprising vertical walls secured together, and a bottom having transverse openings and secured between the lower ends of the vertical walls and comprising side bars longitudinally grooved at their opposite edges and one or more thin sheets extending between said bars and at its edges fitted and secured in said grooves, substantially as described.

9. A rectangular shipping-crate having a bottom, a top frame, a bottom frame, each frame being of the same dimensions and formed by bars in the form of open molding rigidly secured together at their ends and the thin vertical veneer walls extending between and connecting said frames and at their ends edges inserted longitudinally directly into the top and bottom edges respectively of and secured in said bars, said walls being vertically slanted.

10. A shipping-crate having a bottom, and upper and lower frames connected by vertical walls secured thereto, and a cover composed of side bars adapted to fit within the upper frame and longitudinally grooved and a slatted wall connecting said side bars and at its edges fitted and secured in said grooves, substantially as described.

11. A rectangular shipping-crate comprising a bottom and vertical walls all secured together, each wall composed of a panel of two longitudinal bars having their opposite edges longitudinally grooved, and one or more sheets of veneer between and connecting said bars and at the opposite edges fitted and secured in said grooves, said bars secured together at their ends to form the upper and lower frames, the lower frame, at its inner edges beveled or inclined inwardly and outwardly, and the upper frame correspondingly beveled at its outer edges, so that the crates can nest one on the other, substantially as described.

700,997. DOUBLE-SHAFTING MACHINE. ARTHUR F. WOLFE, Brooklyn, N. Y. Filed July 9, 1901. Serial No. 57,000. (No model.)

Claim.—1. In a machine for reaming boxes, the combination of two sets of compensating levers, a pair of reaming-levers fulcrumed to one set of said compensating levers, adjustable fulcrums carried by one set of levers, two cams adapted to engage respectively with said two sets of levers, means for laterally adjusting the fulcrum-carrying levers, means for moving the reaming-levers toward and from the form, and means for connecting the two sets of compensating levers, substantially as and for the purpose specified.

2. In a machine for reaming boxes, the combination of an upper and lower set of compensating levers, a pair of reaming-levers fulcrumed to the upper set of compensating levers and carrying reaming-rolls at their outer ends, rotary cams adapted to act on the inner ends of said reaming-levers for moving the reaming-rolls toward and from the box-form, adjustable fulcrums carried by the lower set of levers and to which the upper set of levers is pivoted, a cam-shaft, a cam adapted to engage with the lower set of levers, an upper cam slidably mounted on the shaft and adapted to be thrown into and out of contact with the upper set of levers, means for laterally adjusting the lower set of levers, and means for connecting and disconnecting the two sets of levers, substantially as and for the purpose specified.

3. In a machine for reaming boxes, the combination of two sets of compensating levers, a pair of reaming-levers fulcrumed to one set of said compensating levers, and carrying the reaming-rolls, cams adapted to act on said reaming-levers for moving the rolls to be moved toward and from the form, means for imparting a rotative movement of rotation to said cams from the driving-shaft of the machine, adjustable fulcrums for one set of levers carried by the other set of levers, two cams adapted to engage

respectively with said two sets of levers and one of said cams being adapted to be thrown into and out of engagement with its corresponding set of levers, means for laterally adjusting the fulcrum-carrying set of levers, and means for connecting the two sets of compensating levers, substantially as described.

4. In a machine for reaming boxes, the combination of an upper and lower set of compensating levers, a pair of reaming-levers fulcrumed to the upper set of compensating levers and carrying reaming-rolls at their outer ends, cams adapted to act on the inner ends of said reaming-levers, adjustable fulcrums carried by the lower set of compensating levers and to which the upper set of levers is pivoted, means adapted to engage respectively with the upper and lower sets of compensating levers and of which the upper cam is adapted to be thrown into and out of connection with the upper set of levers, means for laterally adjusting the lower set of levers, means for connecting and disconnecting the two sets of levers, a driving-shaft, a connection between said driving-shaft and the cams for the reaming-levers, a tumbler, a clutch mechanism, and operative connection between said tumbler and the clutch mechanism permitting the tumbler to be partially depressed for the purpose of pressing the box firmly against the form before the machine is set in motion, substantially as described.

5. In a machine for reaming boxes, the combination of two sets of compensating levers, a pair of reaming-levers fulcrumed to one set of said compensating levers, a cam adapted to act on said reaming-levers for moving their reaming-rolls to be moved toward and from the form, means for imparting a rotative and variable movement of rotation to said cams from the driving-shaft of the machine, adjustable fulcrums for one set of levers carried by the other set of levers, two cams adapted to engage respectively with said two sets of levers and one of said cams being adapted to be thrown into and out of engagement with its corresponding set of levers, means for laterally adjusting the fulcrum-carrying set of levers, and means for connecting the two sets of compensating levers, substantially as described.

6. In a machine for reaming boxes, the combination with the reaming-levers, of two sets of compensating levers actuated at one end by cams, and one set of said levers carrying the reaming-rolls, and means for coupling the two sets of levers together to act as a unit, substantially as described.

7. In a machine for reaming boxes, the combination with the reaming-levers, of two sets of compensating levers actuated at one end by cams, and said sets of levers being fulcrumed together, and one set carrying the reaming-rolls, means for coupling and uncoupling the levers at a point between the fulcrums and the connection with the reaming-levers, and means for laterally adjusting one set of levers about its fulcrum, substantially as described.

8. In a machine for reaming boxes, the combination with the reaming-levers, of two sets of compensating levers, two cams for actuating said

loven, of which the one can be adjustable toward and from the other while in continuous connection with the same, and means for coupling the two sets of lovens together to act as a unit, substantially as described.

9. In a machine for cleaning boxes, the combination with the cleaning-loven, of two sets of compensating lovens, of which the one set carries the cleaning-loven, two means for actuating said compensating lovens, of which the one can be adjustable toward and from the other while in continuous connection with the same, while the other can be movable to align the ends of its corresponding set of lovens, and means for coupling the two sets of lovens together to act as a unit, substantially as described.

700,998. THE PLATE. BENJAMIN WOLFAWTER, Chicago, Ill. Filed Sept. 30, 1891. Serial No. 77,007. (No model.)

Claim.—1. A plate provided on its upper surface with a plurality of separated protuberances, the upper surface of which constitutes the rail-bearing surface.

2. A plate provided on its upper surface with a plurality of separated protuberances, the upper surface of which constitutes the rail-bearing surface, and on its under surface with its engaging flanges.

3. A plate provided on its upper surface with a plurality of separated protuberances, the upper surface of which constitutes the rail-bearing surface, and holding prongs or flanges cut from the body of the plate and bent downwardly therefrom.

4. A plate provided on its upper surface with a plurality of separated protuberances, the upper surface of which constitutes the rail-bearing surface, and on its under surface with its engaging flanges arranged parallel with the side margins thereof, and holding prongs cut from the body of the plate between said flanges and bent downwardly therefrom.

5. A plate provided on its upper surface with a plurality of separated protuberances, the upper surface of which constitutes the rail-bearing surface, and on its under surface at or near the margins thereof with two its engaging flanges and with an intermediate flange or flanges depending from said plate between and parallel with said outer flanges, and holding prongs cut from the body of said plate and bent downwardly from the plate.

6. A plate provided on its upper surface with elevated parts, the upper surface of which constitutes the bearing-surface for the rail and on its lower part with rail-engaging flanges arranged parallel with the side margins of the plate, and holding prongs cut from the body of the said plate between said flanges and bent downwardly therefrom.

7. A plate provided on its lower surface with a plurality of parallel its engaging flanges and on its upper surface with separated protuberances, which form supporting-surfaces for the rail and which are located over one or more of the flanges.

8. A plate provided on its upper surface with a plurality of hollow separated protuberances, the upper surface of which constitutes the rail-bearing surface.

9. A plate provided on its lower surface with its engaging flanges and on its upper surface in its parts between said flanges with a plurality of separated protuberances, formed by striking upwardly the metal of the plate, and which form rail-supporting surfaces.

10. A plate provided on its upper surface with a plurality of separated protuberances, the upper surface of which constitutes the rail-bearing surface, and on its lower surface with rail-engaging flanges, certain of said protuberances being located on the plate over one or more of the

flanges, and others of said protuberances being located in the parts of the plate between the flanges and being struck up from the metal of the plate.

11. A rolled-metal plate provided with its engaging flanges which extend throughout the length of the plate parallel with the side margins thereof, and separated protuberances on the upper surface of the plate, the upper surface of which constitutes the rail-bearing surface, certain of said protuberances being located directly over the flanges and holding prongs cut from the body of the plate between said flanges and bent downwardly therefrom.

12. A rolled-metal plate provided with its engaging flanges, which extend throughout the length of the plate parallel with the side margins thereof, and separated protuberances on the upper surface thereof, of the upper surface of which constitutes the rail-bearing surface, certain of said protuberances being located directly over the flanges and being spaced along said flanges, and others thereof being located between the flanges and made hollow with their upper walls no thicker than the body of the plate.

13. A rolled-metal plate provided with its engaging flanges which extend throughout the length of the plate parallel with the side margins thereof and adjacent to said margins, intermediate flanges parallel with said outer flanges, separated protuberances on the upper surface of the plate, the upper surface of which constitutes the rail-bearing surface, certain of said protuberances being located directly over the intermediate flanges and spaced at equal distances apart, and holding prongs cut from the body of the plate between said intermediate flanges and bent downwardly therefrom.

14. A rolled-metal plate provided on its upper surface with separated protuberances, the upper surface of which constitutes the rail-bearing surface, and prongs cut from the body of the plate and bent downwardly therefrom, said prongs being provided on their lower ends with bars.

15. A plate provided with means for attaching it to a tie, and provided on its upper surface with hollow separated protuberances, the upper walls of which constitute the bearing-surface of the plate, said protuberances being irregularly spaced upon the plate.

16. A plate provided on its upper surface with a plurality of separated circular protuberances.

700,999. MULTIPLE MECHANISM FOR LOCKING. HORACE WYMAN and ALBERT A. GORDON, JR., Worcester, Mass., assignors to GORDON & KNOLLEN Lock Works, Worcester, Mass., a Corporation of Massachusetts. Filed June 10, 1891. Serial No. 68,944. (No model.)

Claim.—1. In a lock, a main pattern-carrier with indicator, a change-lever adapted to be moved by said indicator, and pawls adapted to move the pattern-carrier in either direction, and means between said change-lever and said pawls to reverse the direction of movement of said main pattern-carrier, of a multiplier pattern-carrier carrying indicators to prevent the indication of said change-lever, and means said main pat-

tern-carrier to continue its movement in the same direction, substantially as shown and described.

2. In a lock, a main pattern-carrier, a pair of reversely-acting ratchet-wheels, on the shaft of said main pattern-carrier, and cooperating pawls to move said ratchet-wheels, of a main change-lever moved by indications on said main pattern-carrier, and intermediate connections between said lever and said pawls, to put either pawl into operative position with its respective ratchet-wheel, substantially as shown and described.

3. In a lock, the combination with a main pattern-carrier, a pair of reversely-acting ratchet-wheels on its shaft, and cooperating pawls to move said ratchet-wheels, and a main change-lever moved by indications on said main pattern-carrier, and intermediate connections between said lever and said pawls, to put either pawl into operative position with its respective ratchet-wheel, of a multiplier pattern-carrier, and intermediate connections between said two pattern-carriers, by means of which the main pattern-carrier is caused to stop at predetermined intervals, and a multiplier controlling-lever, and intermediate connections between said multiplier controlling-lever and said pawls, whereby said lever will put into an inoperative position either pawl, which may be at the time in operative position, substantially as shown and described.

4. In a lock, the combination of a main pattern-carrier, means for moving said main pattern-carrier either forward or backward, an auxiliary pattern-carrier, means under control of the main pattern-carrier for determining the operation of the auxiliary pattern-carrier, controlling device for controlling the movement of the main pattern-carrier, and means intermediate the auxiliary mechanism and said device for determining the operative or inoperative action of the main pattern-carrier.

5. In a lock, the combination of a main pattern-carrier, means for moving said main pattern-carrier either forward or backward, controlling-lever for controlling the operation of the main-pattern-carrier-actuating means, an auxiliary pattern-carrier, means under control of the main pattern-carrier for operating said auxiliary pattern-carrier, a multiplying-arm operable from said auxiliary pattern-carrier, a connector-lever in operative relation to said multiplying-arm, and means connected to said lever to move both controlling-levers to render inoperative the main-pattern-carrier-actuating means.

6. In a lock, the combination of a main pattern-carrier, means for moving it either backward or forward step by step to the extent desired, controlling-lever for determining the movement of the main pattern-carrier, a multiplier pattern-carrier controlled in its operation from the main pattern-carrier to determine the position of each of the controlling-levers, an auxiliary pattern-carrier also controlled in its operation from the main pattern-carrier, and means operable therefrom to act upon both controlling-levers to render inoperative the main-pattern-carrier-actuating means.

701,000. FILE-CABINET. CARL P. W. ANDER, Bridgeport, Conn. Filed July 31, 1891. Serial No. 73,571. (No model.)

Claim.—1. In a device of the character described, the combination with side plates having inclined oblique hark, of rods for partition comprising downwardly-inclined flanges adapted to engage the hark and removable only with an upward and outward movement, and horizontal flanges extending directly outward from the upper edges of the inclined attaching device.

2. In a device of the character described the combination with side plates having upwardly-inclined oblique hark closed at the ends, of rods for partition comprising downwardly-inclined flanges adapted to engage the hark and removable only with an upward and outward movement, and horizontal flanges extending directly outward from the upper edges of the inclined flanges.

3. In a device of the character described the combination with side plates having upwardly-inclined oblique hark closed at the ends, of rods for partition comprising downwardly-inclined flanges adapted to engage the hark and removable only with an upward and outward movement, and

horizontal flanges extending directly outward from the upper edges of the inclined flanges, and rigid partition adapted to rest on the horizontal flanges.

701,001. ORB-CRUSHER. ROBERT E. AKIN, Whittey Harbor, N. S. W. Filed Aug. 12, 1891. Serial No. 73,493. (No model.)

Claim.—1. An orb-crusher comprising crushing-rolls acting against each other, whose working surfaces and bearings are in alignment with each other.

2. An orb-crusher comprising crushing-rolls acting against each other whose bearings and working surfaces are in alignment with each other and which are relatively so located that transverse planes passing centrally through said working surfaces will pass centrally through said bearings.

3. An orb-crusher comprising crushing-rolls which act against each other, shafts to which said rolls are attached, and bearings for said shafts of which those nearest the rolls are in alignment with the working surfaces of the rolls.

4. An orb-crusher comprising a main frame, disked or recessed crushing-rolls, shafts to which said rolls are attached and a bearing for each of said shafts mounted on said main frame at the recessed side only of its associated roll, said bearings being located in alignment with the working faces of said rolls.

5. An orb-crusher comprising a main frame, disked or recessed crushing-rolls, shafts to which said rolls are attached, a bearing for one of said shafts mounted on the main frame, a bearing for the other shaft movable upon said frame and means for yieldingly holding the said shafts and rolls in working relation to each other, the working faces of said rolls being in alignment with the bearings of said shafts.

6. An orb-crusher comprising disked or recessed crushing-rolls having bearings on one side thereof only which bearings are in alignment with the working faces of the rolls, and rings or shafts applied to the rolls and forming the working faces thereof.

7. An orb-crusher comprising crushing-rolls of disked or recessed form having bearings on one side thereof located in alignment with the working surfaces of the rolls, said rolls being provided on their concave surfaces with radial flanges or ribs adapted to create air-currents in a direction from the center to the periphery of the rolls when the latter are rotated.

8. An orb-crusher comprising a main frame, a bearing thereon which projects laterally from one side thereof, an arm pivoted to the frame and carrying a second bearing which projects laterally from one side of said arm, disked or recessed crushing-rolls mounted on said bearings, the working surfaces of which are in alignment with said bearings, and spring-actuated means acting on said pivoted arm and holding the rolls in working relation to each other.

9. An orb-crusher comprising crushing-rolls which act against each other and bearings for said rolls arranged in alignment with the working faces thereof, said rolls being provided with integral hubs which turn in said bearings.

10. An orb-crusher comprising crushing-rolls which act against each other, shafts to which said rolls are attached and bearings for said shafts of which those adjacent to the rolls are in alignment with the working faces thereof, said rolls having integral hubs which extend through and turn in said bearings.

701,002. METHOD OF EXTRACTING PRECIOUS METALS FROM THEIR ORES. JAMES E. DE ALMEIDA, London, England. Filed Mar. 14, 1892. Serial No. 64,894. (No specimens.)

Claim.—The process herein described for treating ores containing precious metals and consisting in adding the crushed ore to a solution of sodium chloride, sodium carbonate and potassium cyanide, then forcing through the mass a gaseous mixture of bromine and air and recovering the precious metals from the solution by any known means, such as electrolysis, or not both.

701,008. CULTIVATOR. JOHN B. BARTHELMEY, FORT, Ill., assignor to Avery Manufacturing Company, Fort, Ill. Filed June 6, 1898. Serial No. 894,588. (No model.)

Claim.—1. The combination of the main frame, the vertically-oving pivoted beam, the radius-bar pivoted to the main frame, the suspension-bar pivoted to the beam at points relatively near their rear ends, hinge-like devices for connecting the suspension-bars to the radius-bar, and the lifting-springs each exerting a lifting force upon one of the radius-bars by pulling upon one side of its pivot-end and by pushing upon the other side, substantially as set forth.

2. The combination of the main frame, the vertically-oving pivoted beam, the radius-bar or bars, H, extending upward from and pivoted to the main frame, the suspension-bar J pivoted to the beam at points relatively near their rear ends and detachably connected by hinge-like devices to the upper ends of the radius-bars, the yielding regulator, K, to govern the backward movement of the bars H and J, the lifting-springs, L, pulling forward on the bars or arms H, above their pivots, and the bars, M, connected to the springs L and bearing backward on the radius-bars below their pivots, substantially as set forth.

3. The combination of the main frame, the vertically-oving pivoted beam pivoted at its front end, the lifting-spring mechanism I, the radius-bar H hinged to and projecting upward from the main frame and connected to one end of the spring mechanism, L, the bar M connected to one end to the spring mechanism and at the other end to the arm H, all the suspension-bar J pivoted to the beam at a point in the rear of the front beam-pivot and extending upwardly therefrom and flexibly connected to the radius-bar H above the main frame, substantially as set forth.

4. The combination of the main frame, the vertically-oving pivoted beam pivoted at its front end, the suspension-bar J pivoted to the pivoted beam at a point in rear of the front beam-pivot and extending to a point above the main frame and adapted to swing forward, a stop to limit the forward motion of said bar J, a lifting-spring arranged to draw forward the bar J, means for connecting said spring with said bar, and the movable bar M connected with the spring and sliding to move the bar J in said forward direction, substantially as set forth.

5. The combination of the main frame, the vertically-oving pivoted beam pivoted at its front end, the suspension-bar, J, pivoted to the pivoted beam at a point in the rear of the front beam-pivot, the radius-bar, H, pivoted to the main frame and flexibly connected above said frame to the bar J, said bar, H and J, being adapted to be inclined forward and to be in approximately coincident planes, a stop limiting the movement of said bar, and a spring lifting mechanism connected to said bars substantially as described and comprising means for exerting force both forward and backward relatively to the main frame in effect the lifting, substantially as set forth.

6. In a cultivator, the combination of the beam, a radius-bar from which the beam is suspended, arranged to incline, from the vertical, toward the rear when the beam is in working position, and an approximately horizontal double-acting lifting spring mechanism connected at one end to the radius-bar near its fulcrum, whereby the efficiency of the spring increases, as to the direction in which its force is applied, during the first part of the lifting of the beam, substantially as set forth.

7. In a cultivator, the combination with the main frame, of the vertically-adjustable beam, the radius-arm, the suspension-rod connecting the beam and the radius-arm, and a double-acting lifting spring mechanism connected at one end with the radius-arm near its fulcrum, each connection moving away from a line which would include the fulcrum of the radius-arm and the other end of the spring, as the radius-arm is moved to lift the beam, substantially as set forth.

8. In a cultivator, the combination of the vertically-adjustable beam pivotally suspended at its forward end, a radius-arm, a suspension-rod connecting the beam and the radius-arm and a double-acting spring mechanism having a coiled lifting-spring connected at one end to the radius-bar, the relative disposition of the radius-bar and the spring being such that the efficiency of the spring, as to the direction in which its force is applied to the radius-bar, rapidly increases during the first part of the lifting operation, substantially as set forth.

9. The combination with a machine-frame, of a pivoted beam, a suspension-bar extending upwardly therefrom, a rocking lifting-lever pivoted upon the machine-frame and connected with the suspension-bar, a beam-lifting spring, and means whereby said spring acts upon said lever at two different points and in substantially opposite directions to rock the same and lift the beam.

10. In a cultivator of the hammock type, the combination of the main frame, the pivoted beam adjustable vertically and adapted to swing laterally at its rear end, the radius-bar or lever having a fulcrum on said frame and extending upward therefrom, means for suspending the beam from the upper part of said bar, a pulling member connected with said bar, and a pushing member connected with said bar, said members acting to give the beam an upward movement, and one of said members being a spring adapted to actuate the other member.

11. In a cultivator of the hammock type, the combination of the main frame, the pivoted beam connected with said frame to be adjustable vertically and swinging laterally, a radius-arm mounted on a fulcrum on said frame and extending upward therefrom to a relatively high point above said beam, means for connecting the beam and the upper part of said radius-arm, and two springs connected directly to, and above the fulcrum of, said radius-arm at different heights, the two lines of draft of said springs inclining toward each other and toward a point forward of the lower part of said radius-arm.

12. In a cultivator of the hammock type, the combination of the main frame, and axle, the pivoted beam connected with said frame to be adjustable vertically and swinging laterally, a radius-arm mounted on a fulcrum on said frame and extending upward therefrom to a point relatively high above said beam, suspension means connecting the beam with the upper part of the radius-arm, and suspension means being at the rear of the axle and movable laterally at their lower ends, an approximately horizontal beam-lifting spring connected with said radius-arm at a point near the fulcrum thereof, and a second and regulating spring acting on the beam when in the working position.

13. In a cultivator of the hammock type the combination of the main frame and the axle B, the pivoted beam connected with said frame to be adjustable upward and downward and swinging laterally, a radius-arm mounted on a fulcrum on said frame extending upward therefrom to a relatively high point above said beam, and movable forward from a position in rear of said fulcrum as the beam is lifted, means at the rear of said axle for connecting the beam and the upper part of said radius-arm, and a substantially horizontal spring having a connection with said radius-arm near its fulcrum to force the arm forward.

14. In a cultivator of the class described, the combination with the beam thereof, of the radius-arm, the lifting-spring arranged substantially horizontally and connected to the radius-arm near its fulcrum thereof, a second spring for regulating the shovels when at work, and means for throwing the regulating-spring entirely out of action after the beam commences its forward in opposite position, substantially as set forth.

15. In a cultivator of the class described, the combination of the beam, the radius-arm, the regulator-spring adapted to act upon the beam when in its working position, a lifting-spring, and device connecting one end of the lifting-spring with the radius-arm, the connection of such device with the radius-arm being movable to and away from a line which includes the fulcrum of the radius-arm and the end of the spring to which said connecting device are united, substantially as set forth.

16. In a cultivator of the class described, the combination with the frame and beam thereof, of beam-suspending devices mounted by a suitable fulcrum on said frame, a lifting-spring connected to said suspending devices, and adapted to vibrate to and from a line which is radial to the fulcrum of the suspending devices and includes the center end of the spring, a coiled spring connected to said suspending devices, and adapted to regulate the shovels when in their working position, and means for throwing said coiled spring out of operation when the beam is lifted, substantially as set forth.

17. In a cultivator of the class described, the combination with the

beam thereof and suspension-bar, of a radius-arm having two members projecting in different directions from its axis, a regulator-spring controlling the position of the shovels when at work and connected to one of the said members of the radius-arm, and a lifting-spring connected with the other member of said radius-arm, substantially as set forth.

18. In a cultivator of the class described, the combination with the beam thereof, of a radius-arm connected with the beam, a suspending rod for the beam, a spring, means for connecting the spring to the radius-arm on one side of its axis, means for connecting said spring to the radius-arm on the other side of its axis, whereby the spring can both push and pull around said axis, and a second spring connected to the beam-suspending device and adapted to control the shovels when in working position, substantially as set forth.

19. The combination of the main frame, the pivoted beam vertically adjustable relative to the frame, the radius-arm pivotally connected to the main frame and extending upward therefrom, means for suspending the beam from the said radius-arm, the arm H connected to the radius-arm, the sliding bar pivoted to the arm H and adapted to press backward substantially on the line of the pivot of the radius-arm, and also below B, and the spring connected at one end to the sliding bar, and at the other end connected with the radius-bar, substantially as set forth.

20. In a cultivator of the class described, the combination of the beam-suspending rod, the radius-arm on the frame having a connection with said rod and an arm or extension extending below its fulcrum, the beam lifting or elevating spring, and means for imparting pressure from the spring to the said arm or extension below the fulcrum to move the upper end of the radius-arm forward, substantially as set forth.

21. In a cultivator of the class described the combination with the beam pivotally supported at its front end, of a radius-arm, a beam-suspending rod pivoted to the beam at a point behind its front pivot and connected with the radius-arm, a lifting-spring, a pulling connection or attachment between one end of the spring and the radius-arm on one side of its fulcrum, and a pushing connection or attachment between the spring and the radius-arm and arranged to push on a line on the other side of the fulcrum from that on which the pulling connection operates, substantially as set forth.

22. In a cultivator, the combination with the frame, of a beam pivotally supported near its front end, a radius-arm, a suspension-bar connecting the upper end of the radius-arm and the beam at a point in rear of the front beam-pivot, the radius-arm and suspension-bar being arranged to swing, whereby the beam is adjusted vertically, and a lifting-spring having at each end movable operating means with the beam, whereby the force of the spring is applied from both its ends during the lifting operation, substantially as set forth for the purposes set forth.

23. The combination of the frame, the beam pivotally supported at its front end and vertically adjustable relative to the frame, a double-acting spring-lift mechanism for the beam, a movable support or attachment for one end of the spring, means connecting said support or attachment with the rear part of the beam, a movable support or attachment for the other end of the spring, and means for connecting the last said support or attachment also with the rear part of the beam at points behind the front beam-pivot, whereby the elastic force at each end of the spring is brought to bear upon the rear part of the beam, substantially as set forth.

24. The combination of the main frame, the vertically-adjustable beam, the coupling interposed between the front end of the beam and the frame, a double-acting spring lifting mechanism connected with the rear end of the beam, and comprising a spring, a movable support or attachment for one end of the spring, and a movable support or attachment for the other end of the spring, a radius bar or arm pivoted to the main frame, means connecting the two movable spring supports or attachments to the radius-arm substantially as described, whereby the force of the spring as applied to the radius-arm through both of said supports or attachments tends to move it in one direction, and means independent of the said coupling for connecting the radius-arm to the cultivator-beam at a point in the rear of the coupling, substantially as set forth.

25. The combination of the main frame, the cultivator-beam pivotally supported at its front end, means for suspending the rear end of the beam whereby it is free to swing laterally, a double-acting spring lifting mechanism supported on the main frame and held against lateral movement, it comprising a spring and a movable support or attachment for each end of the spring, both of said supports being adapted to be moved by the spring, and means for connecting both of said spring supports or attachments with the beam at or near its rear end at points behind the front beam-pivot, substantially as set forth.

701,004. CULTIVATOR. JOHN B. BARTHELMEY, FORT, Ill., assignor to Avery Manufacturing Company, Fort, Ill. Filed June 6, 1898. Serial No. 894,581. (No model.)

Claim.—1. In a cultivator of the hammock type, the combination

of the main frame, the beam hinged thereto, a radius-bar or lever pivoted to and extending up from the frame, a suspension-bar connecting the radius-bar and beam, and a lifting-spring having two different connections with the radius-bar, through one of which connections it acts as a lifting-spring and through the other of which connections it acts as a regulator when the beam is in working position.

2. In a cultivator of the hammock type, the combination of the main frame, the beam hinged thereto, a radius-bar or lever pivoted to and extending up from the frame, a suspension-bar connecting the radius-bar and beam, a lifting-spring connected with the radius-bar, and means whereby said spring is also operatively joined with the beam through another connection than its first-mentioned connection with the radius-bar, to act as a regulator.

3. In a cultivator of the hammock type, the combination of the main frame, the beam hinged thereto, a radius-bar or lever pivoted to and extending up from the frame, a suspension-bar connecting the radius-bar and beam, a lifting-spring connected with the radius-bar, and means whereby said spring is connected operatively with the radius-bar at a point above its first-mentioned connection to act as a regulator.

4. In a cultivator, the combination of the main frame, a beam hinged thereto, a radius-bar pivoted to and extending up from the frame, a suspension-bar, regulating device comprising a spring for controlling the position of the beam while working, and means whereby said spring is also operatively connected with the radius-bar to serve as a lifting-spring.

5. In a cultivator, the combination of the main frame, a beam vertically adjustable relative to the frame, the upwardly-extending radius-bar pivotally connected with the frame, means for suspending the pivoted beam from the radius-bar at a point above the main frame, a regulating connection united with the radius-bar, comprising a spring and an intermediate movable member which limits the backward movement of the radius-bar, and another connection between said movable member and the beam whereby the spring also serves as a lifting-spring.

6. In a cultivator, the combination of the main frame, a pivoted beam vertically adjustable relative thereto, a pivoted radius-bar rising from the main frame, means for suspending the beam from the radius-bar, and a regulator comprising a spring and pivoted lever connected with the radius-bar for controlling the backward movement of the same, said spring being also arranged to exert lifting force upon the beam.

7. The combination of the main frame, the beam vertically adjustable relative thereto, the pivoted radius-bar extending upward from the frame, means for suspending the beam from the radius-bar, a regulating-spring connected with the radius-bar to limit its backward movement, said connection comprising a pivoted lever, a stop which limits the regulating action of the spring, and means whereby said spring is connected with the beam to exert a lifting force upon the same.

9. The combination of the main frame, the beam vertically adjustable relative thereto, a pivoted radius-bar extending upward from the beam, means for suspending the beam from the radius-bar, a connection with the radius-bar for limiting its backward movement, a lifting-spring for the beam, means whereby said spring is acted with said regulating connection to control the vertical movement of the beam when in working position and a positive stop for limiting the downward movement of the beam beyond a certain point.

10. The combination of the main frame, the pivot-beam vertically adjustable relative thereto, a radius-bar pivoted to the main frame, means for suspending the beam from the radius-bar, a connection for the beam and the radius-bar for controlling their movement when in working position, a spring for elevating the beam, means connecting the spring and said regulating connection whereby the latter is permitted to yield, and means for locking the radius-bar against the forward action of the spring when the parts are in working position.

11. The combination of the main frame, the beam vertically adjustable relative thereto, a pivoted radius-bar extending upward from the frame, means for suspending the beam from the radius-bar, a connection for the radius-bar and the beam when in working position, a link which tends to hold the parts in working position but yieldable to permit them to be lifted by the operator, and a spring connected both with the said regulating connection and the said link.

12. The combination of the main frame, the beam vertically adjustable relative thereto, the radius-bar, means for suspending the beam from the radius-bar, a lifting-spring connected with the radius-bar above its pivot, means connecting the spring with the radius-bar below its pivot whereby each end of the spring has an operative connection with the beam to lift the same, the connection for limiting the movement of the beam when in working position, and means joining the said regulating connection with the spring whereby the latter operates also as a regulating-spring.

13. The combination of the main frame, the beam vertically adjustable relative thereto, means for suspending the beam adjustably from a point above the main frame, and connected to the beam near the rear end thereof, a spring exerting force in one direction through the said rear suspending device to elevate the beam, means moving in the opposite direction and actuated by the spring to assist in elevating the beam, and a stop or holder for preventing the beam from moving downward beyond the desired limit, substantially as set forth.

14. The combination of the main frame, the beam vertically adjustable relative to the frame, means connected to the beam, near the rear end thereof, for suspending it from a point above the main frame, a spring exerting force from one of its ends, through the said rear suspending device, to elevate the beam, a sliding bar connected with the other end of the spring, and also with the beam-suspending device, and arranged, substantially as described, to lock each device against forward movement when the beam is in working position, and also serving, when the beam is being lifted to transmit to the suspending device the force of the spring from that end with which it is connected, to assist in lifting the beam, substantially as set forth.

15. The combination, in a cultivator, of the main frame, the vertically-adjustable beam, the radius-bar H connected to the beam, the bar I, the arm A, the regulator K connected to the radius-bar, and the spring connected with the regulator, and also with the said parts I and H, substantially as set forth.

16. The combination, in a cultivator, of the main frame, the vertically-adjustable beam, the means for suspending the rear end of the beam, the lifting-spring for exerting in one direction a lifting force upon the beam, means for transmitting from said spring power in the opposite direction also for lifting the beam, and the holder K connected with the said power-transmitting means, substantially as set forth.

17. The combination of the main frame, the vertically-adjustable beam, a radius-bar, means for suspending the rear end of the beam from the radius-bar, a spring drawing upon the radius-bar to lift the beam, a sliding bar M connected with the radius-bar, a holder K to limit the downward movement of the beam when in working position, and a lever N pivotally connected with the bar M, to which lever are connected both the spring and the regulator, substantially as set forth.

18. The combination of the main frame, the laterally-swinging, vertically-adjustable, cultivator-beam, beam-suspending device, a spring, a connection interposed between one end of the spring and the beam-suspending device, through which the spring is adapted to exert a lifting action on the beam when it is rising, and a connection between the other end of the spring and the beam-suspending device, adapted to regulate the beam when in working position, substantially as set forth.

19. The combination of the main frame, the laterally-swinging, vertically-adjustable, cultivator-beam, the beam-suspending device extending upward and swinging forward when the beam rises, and a combined lifting and regulating spring, having device connected operatively between

one end thereof and the beam through which the spring tends to hold the beam in working position, and device interposed between the other end thereof and the beam-suspending device through which the spring acts to lift the beam to its elevated position, substantially as set forth.

20. The combination of the main frame, the laterally-swinging, vertically-adjustable, cultivator-beam, a combined lifting and regulating spring, device interposed between one end of said spring and the beam-suspending device, through which the spring acts to lift the beam from its working position, and a chain interposed between the other end of the spring and the beam-suspending device and through which said spring acts to hold the beam in its working position, substantially as set forth.

21. The combination of the main frame, the laterally-swinging, vertically-adjustable, cultivator-beam, the radius-bar on the frame, the suspending rod or bar for the beam, the spring connected to said radius-bar, a supplemental vibrable lever connected to this spring, and means connected to said supplemental lever for holding it in position against the tension of the spring, substantially as set forth.

22. The combination of the main frame, the laterally-swinging, vertically-adjustable, cultivator-beam, the radius-bar on the frame, the spring connected to the radius-bar, a lever in front of the radius-bar and connected to the spring, said lever being adapted to vibrate and to move the forward end of the spring forward, substantially as set forth.

23. In a cultivator of the class described, the combination of the radius-bar, the beam-suspending rod, the spring (connected to the radius-bar, the vibrable lever in front of the radius-bar having one end connected to the spring and adjustable device connected to the other end of said lever for varying the action of the spring, substantially as set forth.

24. In a cultivator of the class described, the combination of the radius-bar, the beam-suspending rod, the spring, a chain connected to the radius-bar at a relatively high point extending downward, and connected with and receiving power from the spring, a swinging lever connected to the end of the spring, and a toothed bar for varying the position of the spring, substantially as set forth.

25. In a cultivator of the class described, the combination of the beam, the beam-suspending device, consisting of the radius-bar and the beam-suspending rod, the beam-lifting spring connected at one end to the said beam-suspending device, the hinged lever for the opposite end of the spring, and the holder K connecting the lever with the beam-suspending device, substantially as set forth.

26. In a cultivator of the class described, the combination with the beam thereof, of the radius-bar, means for connecting said beam and bar, the spring connected to the radius-bar at a point relatively remote from its fulcrum, and means connecting the spring to the radius-bar at another point relatively near the fulcrum, whereby said spring is adapted to both control the beam when in working position and to elevate it therefrom to its uppermost position, substantially as set forth.

27. In a cultivator of the class described, the combination with the beam thereof, of the radius-bar, the spring connected with the radius-bar near its fulcrum for lifting the beam, the connection interposed between the radius-bar and the said spring, and means for varying the connection between the regulating device and the spring, whereby the pull of the spring upon said device is adjusted, substantially as set forth.

28. In a cultivator of the class described, the combination with the beam thereof, of a radius-bar having two arms projecting in different directions from its axis, a spring, means for connecting said spring with one of the arms of said radius-bar, and means connecting the said spring with the other arm of said bar, one of said connections transmitting power from the spring for sustaining the beam in working position, and the other transmitting power from the spring for lifting the beam away from working position, substantially as set forth.

29. In a cultivator of the class described, the combination with the beam thereof, of a radius-bar having two arms projecting in different directions from its axis, a spring, means for connecting said spring with one of the arms of said radius-bar, means for connecting the said spring with the second arm of the radius-bar, and another and separate connection between the spring and the second arm of the radius-bar, substantially as set forth.

30. In a cultivator, the combination of the main frame, the beam pivoted thereto near its forward end, the beam-suspending device connected with the rear portion of the beam and consisting of a radius-bar pivoted to the frame and extending upward, and a suspension-rod between the radius-bar and the beam, a spring which serves to regulate the depth to which the shovel carried by the beam shall dig, a stop device arranged to determine the normal depth of digging, but which may be forced to permit deeper digging, and a positive stop for limiting the depression of the beam, substantially as set forth.

31. The combination of the frame, the vertically-adjustable beam, a radius-bar, means for suspending the beam from the said bar, a lifting-spring and locking means interposed between the radius-bar and the end of the spring remote from said bar, and arranged to lock or hold the

bar against forward movement when the parts are in working position, such lock being yieldable or breakable by the action of the operator in moving the parts to rising position, substantially as set forth.

32. The combination of the frame, the vertically-adjustable beam, means for suspending the beam from the frame, a lifting-spring, a movable connection between one end of the spring and the beam-suspending device and connection consisting of two parts or members hinged or pivoted together, a stop whereby said parts are rendered rigid relative to each other, whereby the spring may transmit its force through them to the beam, and connection between one of the said pivoted or hinged parts and the beam-suspending device and arranged to move said parts relative to each other upon their hinge or pivot against the action of the spring, substantially as set forth.

701,006. CULTIVATOR. JOHN R. BARTHOLOMEW, Perth, Ill., assignor to Avery Manufacturing Company, Perth, Ill. Filed Feb. 14, 1897. Serial No. 684,681. (No model.)

Claim.—1. In a cultivator, the combination with the frame and the pivot-beam having its rear end vertically adjustable and swinging laterally, of a lever having a fulcrum on and extending upward from said frame, means for suspending the beam from the upper part of said lever, and a longitudinally-extended forwardly-acting spring connected with the frame and with said lever at the rear of said fulcrum and acting substantially in line with said fulcrum when the beam is in working position.

2. In a cultivator, the combination of the main frame, the pivot-beam curved or extended upward at the front end and pivoted to the main frame in a relatively high horizontal plane, the rear end of the beam being vertically adjustable and adapted to swing laterally, the relatively long standard pivoted in the rear end of the beam and extended to points above the main frame, the lever pivoted to the main frame and extending to the upper end of the standard and flexibly connected thereto, and the horizontally-arranged spring having one end rigidly secured to the main frame at a fixed point in front of the lever, and the other end secured to a bar which is connected to the lever, said parts being arranged substantially as set forth, to have the beam relieved of the tension of the spring when the shovel are in their normal working position, substantially as set forth.

3. In a cultivator the combination of the main frame, the shovel-beam pivotedly connected with the frame and having its rear end adapted to swing vertically and laterally, the spring rigidly secured to the front part of the main frame and extending horizontally backward therefrom, a hinged lifting-lever extending upward from an axis on the main frame a connection between said lever and the beam, a bar interposed between the spring and the lifting-lever and connected with the lever in rear of its axis, and a stop for said bar arranged to bear against it when the shovel are in their normal working position, substantially as set forth.

4. The combination of the main frame, the bar or standard H, pivotally connected to the beam, the bar or lever I pivoted on an axis on the

main frame and extending directly upward from its axis and pivotally connected at its upper end to the bar H, one or more arms, i, extending backward from said bar or lever I, the spring J secured to the front part of the main frame and extending horizontally backward therefrom, the bar K connected to the spring and extending backward beyond the axis of the lever, I, and pivotally connected to the bar H, and a stop for the downward movement of the bar K, substantially as set forth.

5. In a cultivator, the combination of the main frame, the beam pivotally connected to the frame and having its rear end adapted to swing both laterally and vertically, a lever I, means connecting said lever to the rear end of the beam, the spring, the bar K between the spring and the lever adapted to lie in the line of the point of connection between the bar K and the lever I and the point of fastening for the spring, and a stop, as at P, for the bar K, substantially as set forth.

6. The combination with the main frame, the beam pivoted thereto and vertically adjustable, the lever I pivoted on the main frame and having an arm i extending rearward beyond its pivot, the standard connecting the rear part of the beam with the upper portion of the lever I, and a lifting-spring arranged substantially horizontally and connected with the said rearward-extending arm i, substantially as set forth.

7. In a cultivator, the combination of the main frame, the beam arranged to swing laterally and vertically, beam-suspending device pivoted on said frame, and a spring acting continuously in a forward direction upon the beam-suspending device and having its line of action, when the beam is in working position, in line with the pivot of said device, and having its line of action when the beam is elevated on a line concentric to the said pivot, substantially as set forth.

8. In a cultivator, the combination of the main frame, the beam arranged to swing laterally and vertically, beam-suspending device pivoted on said frame, a spring acting continuously in a forward direction upon the beam-suspending device and having its line of action, when the beam is in working position, in line with the pivot of said device, and having its line of action when the beam is elevated on a line concentric to said pivot, and a stop for arresting the movement of the spring when in its first-mentioned position, substantially as set forth.

9. In a cultivator, the combination of the main frame, the beam arranged to swing laterally and vertically, beam-suspending device pivoted on said frame, and comprising a lever pivoted on said frame and having an arm extending to the rear of the pivot, a spring acting continuously in a forward direction upon said arm and having its line of action when the beam is in working position near the line of the main pivot of said device, and having its line of action when the beam is elevated on a line concentric to said main pivot, and a stop for arresting the movement of the spring when in its first-mentioned position, substantially as set forth.

10. In a cultivator, the combination of the frame, the beam, the beam-suspending device pivoted to the frame, and a horizontally-arranged spring acting in one direction only disposed substantially as set forth in relation to the other parts, whereby it exerts tension upon the beam when below its normal working position to regulate the depth of the shovel and also upon the beam when above its normal working position, and a bar or lever actuated by the spring and adapted to relieve the suspending device of the force of the spring when the beam is in its working position and to apply the force of the spring to the beam when it is elevated above or depressed below the normal working position; substantially as set forth.

11. In a cultivator, the combination of the frame, the beam, the beam-suspending device pivoted to the frame, the spring, a fulcrum, and the bar K connected to the spring and to the beam-suspending device, and arranged to rest upon said fulcrum when the beam is in or near its normal working position and to move away from said fulcrum when the beam is remote from its working position, substantially as set forth.

12. In a cultivator the combination of a main frame, a pivot-beam having its rear end vertically adjustable and swinging laterally, a lifting device attached to the beam, a horizontally-extended spring connected to the lifting device and extending forward from the same to a suitable point of attachment, such as the frame, and arranged to have its tension increased as the beam descends, and means for arresting the vertical movement of the spring when the beam is in or near the working position.

13. In a cultivator, the combination of the main frame, the beam pivotally connected therewith and having its rear end adapted to swing as described, lifting device connected with the beam and fulcrumed on the frame, a bar or link connected with said lifting device, a horizontally-extended lifting-spring connected with said bar and extending forward from the same to a suitable point of attachment, such as the frame, and a stop or fulcrum for said bar adapted to arrest it as the beam reaches its normal working position.

701,006. CULTIVATOR. JOHN R. BARTHOLOMEW, Perth, Ill., assignor to Avery Manufacturing Company, Perth, Ill. Filed Feb. 14, 1897. Serial No. 684,681. (No model.)

Claim.—1. In a cultivator, the combination of a main frame, a plow-beam pivoted to the main frame, a two-part lifting device for the beam, the parts of which are movable as to each other, joined together by a hinge or flexible connection, means adjacent to said flexible connection for adjusting the normal working position of the beam, without separating the two parts of the lifting device, and a spring arranged substantially as set forth to have the adjusting device between the spring and the beam, as described.

2. In a cultivator, the combination of the main frame, the plow-beam pivoted to the main frame, the lifting-spring, a lifting-bar connected to the beam and having a permanent working connection with the spring, adjusting device interposed between the spring and the lifting-bar, and provided with means for manual adjustment at any time, whereby the normal working position of the beam can be varied without disconnecting the spring from the lifting-bar, substantially as set forth.

3. In a cultivator, the combination of the main frame, the plow-beam pivoted to the main frame, the lifting-bar connected to the beam, the spring, means for permanently connecting the spring to the lifting-bar having two parts flexibly connected together and movable relative to each other from one position to another without disconnecting the spring from the lifting-bar, and a lock for holding said two parts in either of several positions relative to each other for adjusting the normal working position of the beam, substantially as set forth.

4. In a cultivator, the combination of the main frame, the plow-beam pivoted to the main frame, the lifting-bar for the beam, the yielding holder for the lifting-bar which limits its backward movement, the spring arranged to draw upon the holder, and the adjusting device interposed between the spring and the lifting-bar and permanently connected both to the spring and the bar at all times of adjustment, whereby the operator can effect such adjustment without lifting the beam, substantially as set forth.

5. In a cultivator, the combination of the main frame, the plow-beam hinged to the main frame, the lifting-bar connected to the beam, the spring for drawing upon the lifting-bar and means interposed between the spring and the beam having a lock and a lever or bar controllable by the operator while in his seat, and said means being permanently connected both to the spring and to the beam, for adjusting the beam to and locking it in either of the several working positions without displacing the lifting-bar from its substantially working position, substantially as set forth.

6. In a cultivator, the combination of the main frame, the plow-beam hinged to the main frame, the lifting-bar, the spring for drawing upon the lifting-bar, and two movable bars interposed between the spring and the lifting-bar, and a lock for fastening the last two bars together in any of several positions, substantially as set forth.

7. In a cultivator, the combination of the main frame, the plow-beam hinged thereto, the lifting-bar, the means for supporting or holding the lifting-bar, and the bars or levers O Q interposed between the lifting-

bar and its holding device and provided with an adjustable lock, substantially as set forth.

8. In a cultivator, the combination of the main frame, the plow-beam having its rear end vertically adjustable, the lifting-bar, the support or holder for the lifting-bar, and the bars O and Q interposed between the lifting-bar and its support, one of said bars O and Q being provided with teeth and the other with a pin, substantially as set forth.

9. In a cultivator, the combination of the main frame, the plow-beam having its rear end vertically adjustable, the lifting-bar, the holder for the lifting-bar, and the bars O and Q permanently connected together and to the lifting-bar and provided with a ratchet-lock for sustaining the lifting-bar in any of several positions, substantially as set forth.

10. In a cultivator, the combination of the main frame, the plow-beam having its rear end vertically adjustable, the lifting-bar J extending from the beam to a point above the main frame, the holding-bar H, the spring connected to the said bars J and H, and a vibrating lever mounted on said bars J and H for adjusting the plow-beam vertically while the plow is in operation, substantially as set forth.

11. In a cultivator, the combination of the main frame, the plow-beam having its rear end vertically adjustable, the holding-bar H pivotally connected to the main frame and extending upward therefrom, the bar J pivotally connected to the bar H and to the plow-beam, the chain connected to the bars J and H and means permanently connected with and mounted on the bars J and H, and permanently connected with the chain for vertically adjusting the beam and locking it in different positions, substantially as set forth.

12. In a cultivator, the combination of the main frame, the plow-beam having its rear end vertically adjustable, the holding-bar H pivotally connected to the main frame and extending upward therefrom, the lifting-bar J flexibly connected to the holding-bar H, the lever Q pivotally connected to the bars J and H, the chain connected to the said lever, and the locking device interposed between the lever and the lifting-bar J, substantially as set forth.

13. In a cultivator, the combination with the vertically-adjustable plow-beam, of a holding-bar H, a lifting-bar J, the vibrating lever Q and the vibrating locking-bar O, substantially as set forth.

14. In a cultivator, the combination of the vertically-adjustable plow-beam, a holding-bar H, a lifting-bar J, a spring arranged to act on said bars to lift the beam from its working position, means connecting said spring to said bars through which the spring acts on the beam to hold it in its normal working position, and an adjusting device for varying the normal working position of the beam, substantially as set forth.

15. In a cultivator, the combination of the main frame, the plow-beam pivoted to the main frame, means for supporting the rear end of the beam, comprising the bars H and J, a spring for controlling said supporting means and the beam and having a reliable attachment at one end connecting it with the frame, a movable spring-support carried by the said supporting means, and device for adjusting the said spring-support on the beam-supporting means to vary the normal depth at which the shovel shall work, substantially as set forth.

16. In a cultivator the combination of a main frame, a plow-beam pivoted to the main frame, means for supporting the rear end of the beam comprising the rods H J, a supporting-spring, and means, comprising a pivoted member, through which the spring is connected with the said supporting means, arranged to change the effective length of the beam-supporting means by the moving of the said member while the machine is in operation, substantially as set forth.

17. In a cultivator, the combination of the main frame, a plow-beam pivoted to the main frame, means for supporting the rear end of the beam, comprising the rods or bars H and J, a supporting-spring connected with the beam-supporting means, and a hand-lever interposed between the spring and the beam and arranged to change the effective length of the beam-supporting means while the machine is in operation, substantially as set forth.

701,007. CULTIVATOR. JOHN R. BARTHOLOMEW, PAIR, III., assignor to Avery Manufacturing Company, Peoria, Ill. Filed Jan. 29, 1900. Serial No. 2,186. (No model.)

Claim.—1. The combination of the frame, the draft device, the supporting-wheel, adjustable relatively to the draft device and frame, the plow-beam, the double-coiling spring connected with the plow-beam, and the supplemental spring arranged to hold the plow-beam in its normal working position substantially as set forth.

2. The combination of the main frame, the draft device, the supporting-wheel, the plow-beam, the double-coiling spring arranged to lift the plow-beam irrespective of the lateral movements of the latter, and the supplemental spring adapted to lift the plow-beam independently of its lateral movements.

3. The combination of the main frame, the draft device, the plow-beam, the vertically-rocking hinge element for the plow-beam, the hori-

zontal, rocking hinge element for the plow-beam, the lifting-spring arranged to be approximately inactive when the beam is in working position, and the supplemental control-spring at the rear of said vertically-rocking hinge element, both of said springs bearing on the plow-beam without direct connection therewith, substantially as set forth.

4. The combination of the main frame, the draft device, the plow-beam, the vertically-rocking hinge element for the plow-beam, the horizontally-rocking hinge element for the plow-beam, the lifting-spring arranged to be approximately inactive when the beam is in working position, and having means whereby each end of the spring acts to lift the beam and the supplemental control-spring, both of said springs being connected to the said vertically-rocking hinge element for the plow-beam, substantially as set forth.

5. The combination of the main frame, the draft device, the plow-beam, the vertically-rocking hinge element for the plow-beam, the horizontally-rocking hinge element for the plow-beam, the lifting-spring connected to the vertically-rocking hinge element, a lever-like device connected to the said vertically-rocking hinge element, and a supplemental control spring connected to said lever-like device, substantially as set forth.

6. The combination of the main frame, the vertically-swinging laterally-movable plow-beam, and two spring holding devices for the beam at all times inactive relative to the lateral movement of the beam, but adapted to modify the vertical movements thereof, one adapted to exert its force, when the beam is in its working position, on a line approximately radial to the horizontal axis of the beam, and the other to exert its force at said time on a line remote from the radial and at the rear of said axis, substantially as set forth.

7. The combination of the main frame, the plow-beam hinged to the main frame, the spring lifting device for the beam at all times inactive relative to the lateral movements of the beam, and the supplemental control-spring, at all times inactive relative to the lateral movements of the beam, and having its end adjustably connected to the main frame independently of said lifting-spring, substantially as set forth.

8. The combination of the main frame, the plow-beam connected with said frame to swing vertically and laterally by horizontal and vertical hinges, and a beam-controlling spring at the rear of said hinges and held against lateral movement with the beam, said spring being inactive when the beam is elevated and active in the working position of the beam, to contain the beam vertically independent of its lateral movement.

9. The combination of the frame, the plow-beam the wheels adjustable relatively to the plow-beam, the crank-lever R, a lever-like bar O, a link connecting said parts and the link S connecting the crank-lever R to the wheels, substantially as set forth.

10. The combination of the main frame, the plow-beam, the wheels adjustable relatively to the plow-beam, the link R, the crank-lever R, the link Q, a lever-like device as at O pivoted to the main frame, and having a crank P pivoted to the link Q, substantially as set forth.

11. In a cultivator, the combination, with the plow-beam and the main frame, of a tubular hinge element for the beam as at O having a

crank or arm L for a lifting-spring, a crank or arm J for imparting power from a lifting-spring to the hinge element, and a crank arm or lever N for receiving a supplemental spring, substantially as set forth.

12. The combination of the main frame, the wheels adjustable longitudinally of the frame, the driver's seat, and the seat-support connected to the wheels for adjusting them, and having forward-extending arms adapted to bear against the main frame or against abutments thereon when the seat is in its lowest position, substantially as set forth.

13. The combination of the main frame the wheels adjustable longitudinally thereof, the seat and the seat-support hinged to the main frame and connected to said wheels for adjusting them, said seat-support being formed of the flat bars O, O, the laterally-turned bars P rigidly secured to the bars O and hinged to the main frame, said bars O extending forward of the hinge-axis and adapted to bear against the main frame or abutments thereon in front of said axis, substantially as set forth.

14. The combination of the main frame, the plow-beam connected with said frame to swing vertically and laterally by horizontal and vertical hinges, a beam-controlling spring at the rear of said hinges and held against lateral movement with the beam, said spring being inactive when the beam is elevated and active in the working position of the beam to contain the beam vertically independent of its lateral movement, and means for adjusting the suspension-point of said spring vertically.

15. The combination of the main frame, the plow-beam connected with said frame to swing vertically and laterally by horizontal and vertical hinges, a beam-controlling spring at the rear of said hinges and held against lateral movement with the beam, said spring being inactive when the beam is elevated and active in the working position of the beam to contain the beam vertically independent of its lateral movement, and the stretched plate W and rod W' for holding said spring at different heights.

701,008. CULTIVATOR. JOHN R. BARTHOLOMEW, PAIR, III., assignor to Avery Manufacturing Company, Peoria, Ill. Filed Nov. 5, 1900. Serial No. 25,471. (No model.)

Claim.—1. The combination of the plow-beam swinging laterally and movable vertically, the beam-coupling, the controlling-spring supported upon the beam-coupling and acting to sustain the beam when the latter is in working position, and a manual spring-controlling mechanism for said spring extending within reach of the operator in his working position substantially as set forth.

2. The combination of the laterally-swinging vertically-movable plow-beam, the coupling at the front end of the beam, the lifting-spring and the controlling-spring, said springs being arranged substantially as set forth, the one arranged to be inactive or approximately inactive when the beam is in working position, and the other arranged in front of the beam-coupling to be inactive when the beam is elevated from its working position.

abstent, an abutment or stop mounted to move toward and from the controlling-spring, and means for connecting the abutment positively with the main frame of the machine substantially as described.

3. The combination of the plow-beam adapted to be adjusted horizontally and vertically, and the laterally-adjustable control-spring acting upon the beam through the beam-coupling, substantially as set forth.

4. The combination of the laterally and vertically-acting plow-beam, the laterally-adjustable vertically-acting beam-coupling and the control-spring supported independently of the beam and arranged to swing bodily around the horizontal axis of the beam, substantially as set forth.

5. The combination of the vertically-acting plow-beam hinged to an axial support and the control-spring in front of said axial support and arranged to be inactive from the time when the beam leaves its operative or approximately horizontal position, and means for manually controlling the operative resistance of said control-spring from the operator's position, substantially as set forth.

6. The combination of the vertically-acting plow-beam hinged to an axial support, the control-spring and the relatively stationary abutment for said spring, the latter being arranged to be insensitive when the beam departs from its operative approximately horizontal position, and means for manually controlling from the operator's position the position of said abutment, substantially as set forth.

7. The combination of the vertically-acting plow-beam hinged to an axial support, the control-spring and the adjustable positive relatively stationary stop for the control-spring, substantially as set forth.

8. The combination of the vertically-acting plow-beam hinged to an axial support, a control-spring movable bodily up and down when the plow-beam moves vertically, a stationary abutment or stop against which the spring bears when the plow is in working position, and means for manually controlling from the operator's position the position of said abutment, substantially as set forth.

9. The combination of the vertically-acting plow-beam, the hinged-support for the plow-beam mounted on a horizontal axis, a control-spring the two oppositely-acting abutments for said spring both connected to the said hinged-support, and means extending to the operator's position for adjusting one of said abutments, substantially as set forth.

10. The combination of the vertically-acting plow-beam, the coupling on a horizontal axis, the control-spring and the two abutments for the spring both laterally adjustable substantially as set forth.

11. The combination of the plow-beam, the vertically-acting coupling for the beam, the control-spring, the abutment for the spring rigid with the coupling, the opposing abutments for the spring and means for confining the free end of the spring when the abutments are separated from each other, substantially as set forth.

12. The combination of the plow-beam, the vertically-acting coupling for the beam, the lifting-spring arranged to exert an upward force to lift the beam at the rear of the horizontal beam-pivot and a downward force at the front of said pivot, and the supplemental control-spring supported on the coupling independently of the beam, substantially as set forth.

13. The combination of the vertically-acting plow-beam, the control-spring adapted to exert lifting force upon the beam when the latter is in its working position, an abutment for one end of the spring, and two abutments for the other end of the spring, the latter abutments being separable when the spring is inactive, substantially as set forth.

14. The combination with the vertically-acting plow-beam and the control-spring supported independently of the beam and acting vertically upon the beam when it is in its operative position, of the adjustable stop-bar having a hinge connection with the beam and adapted to vary the position of activity of the spring, substantially as set forth.

15. The combination of the vertically-acting plow-beam, the abutment or stop movable with the plow-beam, the relatively stationary stop or abutment, yielding stop device between the two abutments, rigid stop device between the two abutments, and means for bringing the said stop devices alternately into action, substantially as set forth.

16. In a cultivator the combination of the main frame, the plow-beam swingable laterally and vertically, a coupling member between the beam and frame, two arms severally extending from said coupling, a control-spring between said arms for actuating the beam in working position, and an abutment for confining and releasing one of said arms.

17. In a cultivator, the combination of the main frame, the plow-beam pivoted thereto and swingable laterally and vertically, and a manually-controlled compression control-spring acting to support said beam when the latter is in its working position and inactive when the beam is elevated.

18. In a cultivator, the combination of the main frame, the plow-beam pivoted thereto and swingable laterally and vertically, and a manually-controlled compression control-spring for the beam situated in front of the horizontal pivot of the beam.

19. In a cultivator, the combination of the main frame, the plow-

beam pivoted thereto and swingable laterally and vertically, a manually-controlled compression control-spring for the beam, and an abutment on the main frame against which the spring is adapted to act when the beam is in working position, the spring being disconnectible mechanically from said abutment when the beam is in non-working position.

20. In a cultivator, the combination of the main frame, the plow-beam pivoted thereto and swingable laterally and vertically, a compression control-spring for said beam, and a manually-operated pressure-varying device supported on the frame, through which device said spring is controlled, said pressure-varying device being disconnectible mechanically from the spring, the latter remaining in place.

21. In a cultivator, the combination of the main frame, the plow-beam pivoted thereto and swingable laterally and vertically, and a manually-controlled compression control-spring supported on the vertically-vibrating parts connected with the plow-beam and arranged to have both of its ends remain in substantially the same position relatively to the beam while the beam is up or down.

22. In a cultivator, the combination of the main frame, the plow-beam pivoted thereto and swingable laterally and vertically, a manually-controlled abutment on said frame, and a control-spring for the beam arranged to vibrate bodily around the horizontal axis of the beam, said spring acting against said abutment when the beam is in working position.

23. In a cultivator, the combination of the main frame, the plow-beam pivoted thereto and swingable laterally and vertically, a compression control-spring exerting downward pressure in front of the beam-pivot upon parts connected with the beam and acting to support the beam in working position, the beam being swingable laterally while subjected to said pressure, and manual device operative by the rear of the machine in its working position for regulating the working pressure of the spring.

24. In a cultivator, the combination of the main frame, the plow-beam pivoted thereto and swingable laterally and vertically, a compression control-spring acting downward in front of the horizontal pivot of the beam, and a lever controlled by the operator for exerting pressure or resistance upon one end of the spring and movable relatively to the spring to vary said pressure or resistance.

25. In a cultivator, the combination of the main frame, the plow-beam pivoted thereto and swingable laterally and vertically, a compression control-spring acting to regulate the beam when in working position, a vertically-vibrating abutment at one end of the said spring, and means for adjusting said abutment to vary the working pressure of the spring.

26. In a cultivator the combination of the main frame, the plow-beam pivoted thereto and swingable laterally and vertically, a compression control-spring acting downward forward of the horizontal pivot of the beam to regulate the latter in its working position, and means independent of the beam for manually varying the working pressure of said spring.

27. In a cultivator, the combination of the main frame, the plow-beam pivoted thereto and swingable laterally and vertically, a compression control-spring acting downward forward of the horizontal pivot of the beam to regulate the latter in its working position, a movable abutment supported from said frame against which abutment the spring acts when the beam is in working position, and a hand-lever for adjusting said abutment to vary the working pressure of the spring.

28. In a cultivator, the combination of the main frame, the plow-beam pivoted thereto, swingable vertically and laterally, and adjustable laterally, and a manually-controlled compression control-spring acting to support the beam in working position, the controlling means of said spring comprising a laterally-adjustable abutment for the spring, said spring and abutment being separable by the elevation of the beam.

29. In a cultivator the combination of the beam-carrying arch-bar, the plow-beam mounted to swing vertically on a hinge or pivot, the lifting-spring arranged to exert a lifting force on the beam at the rear of said hinge, and the bar 45 engaged and forced downward by said spring, exerting a downward force at the front of said hinge to aid in containing the beam, and bearing backward at its upper part against the transverse portion of said arch-bar, substantially as set forth.

701,009. LIFE-BOAT-LAUNCHING DEVICE. JAMES W. BEE, San Francisco, Cal. Filed Oct. 10, 1901. Serial No. 73,191. (No model.)

Claim.—1. In a launching apparatus, the combination with track-rails, and supports therefor, of a trolley device mounted upon said rails and including a pivoted elevating member normally disengaged from the boat, and adapted to engage and suspend the boat.

2. In a launching apparatus, the combination with track-rails having hinged sections at the ends, and supports for said rails, of a trolley device to travel on the rails, and a pivoted lifting device normally at-

tached to the trolley, and disengaged from a boat and adapted to engage and elevate the boat and suspend it, substantially as described.

3. In a boat-launching apparatus, the combination of overhead tracks, track-sections on the end of said tracks, means by which said sections are supported at their outer ends so that said sections may be continuous with the tracks, boat-supporting trolley-chassis movable on said tracks and sections, and provided with a lever normally disengaged from the boat and adapted to engage and transport the latter, and means by which said sections may be folded back when not in use.

4. In a boat-launching apparatus, the combination with horizontal tracks and movable and extendable thereof, of trolley-chassis movable on said tracks, a lever pivoted on each of said trolley-chassis, said lever having a shorter back-arm, and a longer purchase-arm.

5. In a boat-launching apparatus, the combination of two tracks supported above the surface, pivoted and extendable of said tracks, frames pivoted above the tracks and connected to the outer end of said track-extensions, trolleys movable on said tracks and extensions and means by which the latter and their supports may be folded back when not in use.

6. In a boat-launching apparatus, the combination of two horizontal track-rails, movable track-sections on the ends of said rails, section-supports above said rails adapted to turn in unison with said sections, boat-trolley-carriers upon said rails, carriers upon the sections and means whereby a boat may be shifted from the carriers on the track to the carriers on the sections.

7. In a boat-launching apparatus, the combination of horizontal track-rails, trolley-carriers on said rails, pivoted extensions on the ends of said rails, means for supporting the ends of said extensions, trolley-chassis on the latter and a fall carried by said chassis having one end made fast to the outer ends of said extensions.

8. In a boat-launching apparatus, the combination of parallel trolley-ways separated a distance approximately the length of the boat to be launched, pivoted extensions on said ways, trolleys on said extensions, pivoted A-frames and connections of these frames with the ends of said extensions, said frames and extensions adapted to fold back upon the ways, a fall carried by each of said trolleys, one end of said fall being fast to the outer end of the extension, and a stop upon said standing portion whereby the trolley is forced toward the inner end of the extension when the boat is raised.

701,010. BOAT-SUPPORTER. JAMES W. BEE, San Francisco, Cal. Filed Feb. 12, 1902. Serial No. 67,600. (No model.)

Claim.—In a boat-supporter, the combination of an upward-acting standard, a supporting-bar at the lower end of said standard, a plate pivoted at the upper end of the standard upon a horizontal pivot, and a series of flexible fingers or prongs projecting beyond the upper surface of the plate, as to provide for the plate being insertible beneath the boat-cover at any position therebetween, the pivot of the plate per-

mitting said plate to automatically adjust itself against said under side of the boat-cover, and the flexible prongs or fingers releasably holding the boat-cover to the plate in any position to which said plate may be adjusted beneath the cover.

701,011. MACHINE FOR DOUBLE-SEAMING METAL SHEETS. CHARLES E. BROWN, Syracuse, N. Y. Filed Jan. 6, 1902. Serial No. 63,574. (No model.)

Claim.—1. A machine for double-seaming metal sheets, comprising a vertically-movable platen for supporting the sheets to be united, eccentric pivots supported on the main frame and carrying the platen, means for turning said eccentric to impart vertical movement to the platen, a press-follower facing said platen, dies introduced between the platen and follower and shaped to contain the edges of the sheets at successively-increasing angles, and means for applying pressure to the follower and folding and compressing the edges of the sheets on the dies.

2. A machine for double-seaming metal sheets, comprising a vertically-movable platen for supporting the sheets to be united, said platen disposed beneath and parallel with the platen and pivotedly supported on the main frame, eccentric of corresponding diameter fastened to said platen, parallel arms of equal length fixed to said platen, a rod connecting the free ends of said arms, means for imparting reciprocating motion to said rod, a press-follower facing said platen, dies introduced between the platen and follower and shaped to contain the edges of the sheets at successively-increasing angles, and means for applying pressure to the follower and folding and compressing the edges of the sheets on the dies.

3. A machine for double-seaming metal sheets, comprising a platen for supporting the sheets to be united, a press-follower facing said platen, a main die carried on the face of the follower and provided with a recess for receiving the sheets carried on the platen and with an laterally-declined rim surrounding said recess, a vertically-movable auxiliary die disposed to said main die and having its edges shaped correspondingly to the above-mentioned rim to bend the flange of one sheet over the flange of the companion sheet and turn said flange jointly inward, means for imparting vertical movement to the above-mentioned auxiliary die, and means for applying pressure to the follower.

4. In a machine for double-seaming metal sheets, the combination

of a vertically-movable platen for supporting the sheet to be united, means for uniting said platen at different elevations, a press-follower facing said platen, a main die carried on the face of the follower and provided with a recess for receiving the sheet carried on the platen and with an inwardly-sloped rim surrounding said recess, a vertically-movable auxiliary die disposed in said recess and having its edges sloped correspondingly to the aforesaid rim to bend the flange of one sheet over the flange of the companion sheet and turn said flanges jointly inward, means for imparting vertical movement to the aforesaid auxiliary die, and means for applying pressure to the follower.

5. In a machine for double-seaming metal sheets, the combination of a vertically-movable platen for supporting the sheet to be united, mechanism imparting vertical movement to said platen, a press-follower facing said platen, a main die carried on the face of the follower and provided with a recess for receiving the sheet carried on the platen and with an inwardly-sloped rim surrounding said recess, a vertically-movable auxiliary die disposed in said recess and having its edges sloped correspondingly to the aforesaid rim to bend the flange of one sheet over the flange of the companion sheet and turn said flanges jointly inward, means for imparting vertical movement to the aforesaid auxiliary die, and means for applying pressure to the follower.

6. In a machine for double-seaming metal sheets, the combination of a platen, a clamp securing to said platen the sheet to be united, a press-follower facing said platen, a main die carried on the face of the follower and provided with a recess for receiving the sheet lying upon the top of the platen and with an inwardly-sloped rim surrounding said recess, a vertically-movable auxiliary die disposed in said recess and having its edges sloped correspondingly to the aforesaid rim, means for imparting vertical movement to said auxiliary die, and means for applying pressure to the follower as set forth.

7. In a machine for double-seaming metal sheets, the combination of a platen supporting the sheet to be united, a press-follower facing said platen, a main die carried on the face of the follower and provided with a recess for receiving the sheet lying upon the top of the platen and with an inwardly-sloped rim surrounding said recess and grooves in the face of the recess beveled at corresponding edges and in corresponding directions, a vertically-movable auxiliary die contained yieldingly in the recess of the main die and having its edges sloped correspondingly to the aforesaid rim, wedge-plates interposed between said main and auxiliary dies, means for moving said wedge-plates into and out of the aforesaid grooves, and means for applying pressure to the follower as set forth.

8. In a machine for double-seaming metal sheets, the combination of a vertically-movable platen, a clamp securing to said platen the sheet to be united, means for imparting vertical movement to the platen, a press-follower facing said platen, a main die carried on the face of the follower and provided with a recess for receiving the sheet lying upon the top of the platen and with an inwardly-sloped rim surrounding said recess and grooves in the face of the recess beveled at corresponding edges and in corresponding directions, a vertically-movable auxiliary die contained yieldingly in the recess of the main die and having its edges sloped correspondingly to the aforesaid rim, wedge-plates interposed between said main and auxiliary dies, means for moving said wedge-plates into and out of the aforesaid grooves, and means for applying pressure to the follower as set forth.

9. In a machine for double-seaming metal sheets, the combination of a platen supporting the sheet to be united, a press-follower facing said platen, a main die fastened to the follower and provided with a recess for receiving the sheet lying upon the top of the platen and with an inwardly-sloped rim surrounding said recess and parallel grooves in the face of the recess beveled at corresponding edges and in corresponding directions, a vertically-movable auxiliary die contained yieldingly in the recess of the main die and having its edges sloped correspondingly to the aforesaid rim, wedge-plates interposed between the main and auxiliary dies, a bar connecting said plates to each other, means for moving said bar to carry the wedge-plates into and out of the aforesaid grooves, and means for applying pressure to the follower as set forth.

10. In a machine for double-seaming metal sheets, the combination of a platen supporting the sheet to be united, a press-follower facing said platen, a main die fastened to the follower and provided with a recess for receiving the sheet lying upon the platen and with an inwardly-sloped rim surrounding the recess, an auxiliary die contained yieldingly in the recess of the main die, springs holding the auxiliary die normally seated on the face of the recess, means for depressing the auxiliary die from said normal position, and means for applying pressure to the follower.

11. In a machine for double-seaming metal sheets, the combination of a platen supporting the sheet to be united, a press-follower facing said platen, a main die fastened to the follower and provided with a recess for receiving the sheet lying upon the platen and with an inwardly-sloped rim surrounding the recess, an auxiliary die contained yieldingly in said recess and having its edges sloped correspondingly to the rim of the main

die, springs holding the auxiliary die normally seated on the face of the recess, means for forcing the auxiliary die in a lateral direction, and means for applying pressure to the follower.

12. In a machine for double-seaming metal sheets, the combination of a vertically-movable platen, a clamp securing to said platen the sheet to be united, means for imparting vertical movement to the platen, a press-follower facing the platen, a main die fastened to the follower and provided with a recess for receiving the sheet lying upon the platen and with an inwardly-sloped rim surrounding the recess, an auxiliary die contained yieldingly in said recess and having its edges sloped correspondingly to the rim of the main die, springs holding the auxiliary die normally seated on the face of the recess, means for forcing the auxiliary die in a lateral direction, and means for applying pressure to the follower.

13. In a machine for double-seaming metal sheets, the combination of a vertically-movable platen, a clamp for securing to said platen the sheet to be united, means for imparting vertical movement to the platen, a press-follower facing the platen and provided with vertical perforations, a main die fastened to the follower and provided with perforations disposed concentric in relation to those of the follower, said main die provided in its under side with a recess for receiving the sheet lying upon the platen and with an inwardly-sloped rim surrounding the recess, an auxiliary die disposed yieldingly in said recess and having its edges sloped correspondingly to the aforesaid rim, bolts attached to the auxiliary die and extending through the aforesaid perforations and having their lower and portions fitted closely in the perforations of the main die and upper and portions reduced in diameter and beveled at their junctions with the lower and portions, springs forcing the said bolts upward, means for forcing the auxiliary die downward from the main die and means for applying pressure to the follower as set forth.

14. In a machine for double-seaming metal sheets, the combination of a vertically-movable platen, a clamp securing to said platen the sheet to be united, means for imparting vertical movement to the platen, a press-follower facing the platen and provided with vertical perforations, a main die fastened to the follower and provided with perforations disposed concentric in relation to those of the follower, the under side of said main die provided with a recess for receiving the sheet lying upon the platen and with an inwardly-sloped rim surrounding the recess, an auxiliary die disposed yieldingly in said recess and having its edges sloped correspondingly to the aforesaid rim, bolts attached to the auxiliary die and extending through the aforesaid perforations and having their lower and portions fitted closely to the perforations of the main die and their upper and portions, wedges projecting from the sides of the upper and portions, expansion-springs interposed between the top of the follower and heads of the bolts, movable wedge-plates interposed between the main and auxiliary dies, a lever for moving said wedge-plates, and means for applying pressure to the follower as set forth.

15. A machine for double-seaming metal sheets, comprising a platen for supporting the sheet to be united, a press-follower facing said platen, a main die fastened to the follower, an auxiliary die contained movably under said main die and shaped to partly fold the joining edges of the sheet, means for moving said auxiliary die to different operative positions, a final clamping-plate suspended from said frame, means for moving said plate to and from between the platen and main die, and means for applying pressure to the follower as set forth.

16. In a machine for double-seaming metal sheets, the combination of a vertically-movable platen, a clamp for securing to the platen the sheet to be united, means for moving the platen, a press-follower facing said platen, a main die attached to the follower, an auxiliary die contained movably under the main die and shaped to partly fold the joining edges of the sheet, means for moving the auxiliary die to different operative positions, guides attached to the follower, a frame mounted on said guides, a final clamping-plate suspended from said frame, means for moving said plate to and from between the platen and main die, and means for applying pressure to the follower as set forth.

17. In a machine for double-seaming metal sheets, the combination of a vertically-movable platen, a clamp for securing to the platen the sheet to be united, means for moving the platen, a press-follower facing said platen, a main die attached to the follower, an auxiliary die contained movably under the main die and shaped to partly fold the joining edges of the sheet, means for moving the auxiliary die to different operative positions, guides attached to the follower, a frame mounted on said guides, a final clamping-plate suspended from said frame, means for automatically moving said plate from the platen, means for forcing said plate between the platen and main die, and means for applying pressure to the follower as set forth.

701,012. RENOYAT. ROY W. BROWN and CHARLES A. RENOYAT, Milwaukee, Wis., assignors to Union Electric Manufacturing Company, Milwaukee, Wis., a Corporation. Filed Dec. 16, 1901. Serial No. 88,148. (No model.)

Claim.—1. In a frame for a rheostat, a sheet-metal member in double-L form provided with supporting-legs and adapted to support one or more magnets thereon.

2. In a frame for an electromagnet in a rheostat, a principal member consisting of a strip of sheet metal bent into double-L form having reversely-projecting and portions and a medial transverse portion at right angles thereto.

3. In a rheostat, a frame for an electromagnet and a solenoid, composed of two strips of sheet metal bent and riveted to each other so as to inclose a space and an offset therefrom at one side thereof, the frame of the offset projecting in one side of the space.

4. In a rheostat, a frame for an electromagnet and a solenoid, consisting of two strips of sheet metal bent and riveted to each other so as to inclose a space and an offset therefrom at one side thereof, and means integral with a strip of the frame for securing it to supporting means.

5. In a rheostat, a frame for an electromagnet and a solenoid, consisting of two strips of sheet metal bent and riveted to each other so as to inclose a space and an offset therefrom at one side thereof, and means integral with a strip of the frame for securing it to supporting means.

6. In combination in a rheostat, a strip of sheet metal bent in double-L form, and a plurality of magnets attached thereto one to a free terminal bar of the strip and the other to the medial transverse bar of the strip.

7. In combination in a rheostat, a strip of sheet metal bent in double-L form, a plurality of magnets attached thereto one to a projecting bar of the strip the other to the medial bar, and a swinging armature-hinged to the other projecting bar of the strip.

8. In combination in a rheostat, a strip of sheet metal bent in double-L form, a plurality of magnets attached thereto one to a projecting bar of the strip, the other to the medial bar, a swinging armature-hinged to the other projecting bar of the strip, and a tilting armature-hinged and supported on the last-mentioned bar of the strip.

9. In a rheostat, a switch-arm composed of a strip of sheet metal swaged into form with longitudinal strengthening ribs and with a carbon-holding frame.

10. A switch-arm for a rheostat struck up from sheet metal, and having marginal strengthening-ribs, and a carbon-holding frame.

11. In combination in a rheostat, a switch-arm struck up from sheet metal having marginal ribs and a carbon-holding frame, and a flat spring alongside the arm between said ribs and passing through a slot therefor in the arm and adapted to bear on a carbon in the carbon-frame.

12. In a rheostat, a switch-arm struck up from sheet metal and so mounted at one end as to be capable of swinging in an arc, a concentric ratchet also of sheet metal secured to the switch-arm and an armature-actuated hook engaging said ratchet rotatably.

13. In combination, a switch-arm for a rheostat struck up from sheet metal with marginal ribs and a carbon-holding frame, a flat spring secured to and parallel with the switch-arm between its marginal ribs, and an adjusting-screw turning in and through a struck-up bar on the switch-arm against the spring adapted to adjust the tension of the spring.

14. A rheostat-constructed up from sheet metal and having a rear wall and side walls with integral ears at the corners adapted for securing the rheostat to its support and with struck-up ribs on the side walls.

15. A resistance medium for a rheostat, consisting of a grid struck up from sheet metal in the form of a continuous strip having return-bends, a plurality of parallel medial sections, and parallel terminal sections provided with lateral recesses for receiving supporting-studs thereon.

16. A resistance medium for a rheostat, consisting of a grid struck up from sheet metal in the form of a continuous strip having return-bends and parallel adjacent longitudinal sections and having a longitudinal rib or ribs thereon.

17. In combination in a rheostat, an integral holding-frame member, and a plurality of independent electromagnets mounted on the inte-

gral frame member, the frame member serving to support the electromagnets and forming a part of the magnet-yokes of both electromagnets.

18. In a rheostat, a switch-arm composed of a strip of sheet metal swaged into form with strengthening-ribs and with a frame for a contact-piece.

19. In combination in a rheostat, a switch-arm struck up from sheet metal having a contact holding-frame, and a flat spring secured to the arm and serving the double purpose of an additional support for the arm and of a spring bearing on the contact member.

20. In a rheostat, a resistance medium swaged from sheet metal with strengthening-ribs.

21. A resistance medium for a rheostat, composed of a plurality of sheet-metal grids each grid consisting of a single strip of metal, the strips of all the grids being of uniform width but of varying thicknesses, and connected up electrically.

22. In a rheostat, a frame for a solenoid composed of strips of sheet metal cut and swaged into form and riveted to each other and including a substantially square space, and having a guideway for the solenoid-core extending from one side of the frame.

23. In a rheostat, a switch-arm composed of sheet metal swaged into form and having thereon a frame for a contact-piece.

24. In a rheostat, a switch-arm composed of two strips of sheet metal swaged into form and secured together, and a coiled spring between separated terminal portions of the two strips.

25. In a rheostat, a switch-arm composed of two strips of sheet metal swaged into form and secured together, and a coiled spring between separated terminal portions of the two strips.

701,018. CLOTH-GUIDE FOR SEWING-MACHINES. SARAH E. BARKER, Aurora, Ill. Filed Feb. 4, 1901. Serial No. 88,088. (No model.)

Claim.—1. An attachment for sewing-machines constructed to sew together the overlapping margins of two pieces of fabric or the like, comprising a presser-foot having one margin plain and provided at its other margin and adjacent to the needle-aperture of said foot with an integral inwardly-facing guide-shoulder, extending below the plane of the bottom face of the presser-foot and adapted to engage the folded margin of one of the pieces of fabric, and a guide-flange on the cloth-plate located in front of the presser-foot and at one side of the line of the needle, said flange having a guide-surface opposing the guide-surface of the presser-foot and adapted to engage the folded margin of the other piece of fabric, and the flange being provided with a horizontal part which extends laterally toward the guide-shoulder on the presser-foot and is located over and substantially parallel with the cloth-plate.

2. An attachment for sewing-machines constructed to sew together the overlapping margins of two pieces of fabric or the like, comprising a presser-foot having one margin plain and provided at its other margin with an integral, inwardly-facing guide-shoulder extending below the plane of the bottom face of the presser-foot and adapted to engage the folded margin of one of the pieces of fabric, and a guide-flange integral with and projecting above the cloth-plate and located in front of the presser-foot, said flange having an inwardly-facing guide-surface opposing the guide-shoulder of the presser-foot and adapted to engage the folded margin of the other piece of fabric and the flange being also provided with an integral horizontal part which extends laterally toward the guide-surface on the presser-foot and is located over and substantially parallel with the cloth-plate, the rear margin of said horizontal part of the flange being inclined and obliquely facing the guide-shoulder on the presser-foot.

701,014. CURTAIN-STRETCHER. CHARLES C. GARDNER, Chicago, Ill. Filed Dec. 9, 1901. Serial No. 88,180. (No model.)

Claim.—1. In a curtain-stretcher, the combination of divided side bars or rails edgewise folding a stiffening-plate for the joint of each side bar or rail overlapping the abutting ends of the bar or rail sections on each side of the joint, depending pins or pivots for each stiffening-plate, one pin or pivot at each end of the plate, the pins or pivots of one plate having a greater length than the thickness of the bar or rail and said pins or pivots being secured to the bar or rail and extending from side bar or rail to side bar or rail and crossing the bars or rails at the joints on the opposite face of the bar or rail to the stiffening-plate, clamping-bolts one for each end of the cross-brace or stiffening-bar, passing through the cross-brace or stiffening-bar, between the abut-

they ends of the sections of the side bar or rail, and through the stiffening-plate one bolt having a greater length than the combined thickness of the cross-brace or stiffening-bar and the two side bars or rails when folded, and tightening-nuts for the clamping-bolts, substantially as described.

2. In a certain-stretcher, the combination of divided side bars or rails edgewise folding each bar or rail at its shutting end having a rounded inner corner, a stiffening-plate for the joint of each bar or rail overlapping the shutting ends of the bar or rail sections on each side of the joint and having on each side depending edges or flanges engaging the side faces of the bar or rail, depending pins or pivots for each stiffening-plate, one pin or pivot at each end of the plate the pins or pivots of one plate having a greater length than the thickness of the bar or rail and each provided with a head, a cross-brace or stiffening-bar extending from side bar or rail to side bar or rail and crossing the bars or rails at the joints on the opposite face of the bar or rail to the stiffening-plate, clamping-bolts, one for each end of the cross-brace or stiffening-bar, between the shutting ends of the sections of the side bar or rail, and through the stiffening-plate, one bolt having a greater length than the combined thickness of the cross-brace or stiffening-bar and the two side bars or rails when folded, tightening-nuts for the clamping-bolts of the cross-brace or stiffening-bar, detachable end bars or rails and removable clamping-bolts for the crossing corners of the side bars or rails and the end bars, or rails for folding the divided side bars or rails edgewise one over the other and on the cross-brace or stiffening-bar and pinning the end bars or rails on the folded sections of the side bars or rails and thereby folding the stretcher, as a whole, in a compact form for shipment and storing away with the retaining-pins protected, substantially as described.

3. In a certain-stretcher, the combination of divided side bars or rails edgewise folding each bar or rail at its shutting end having a rounded inner corner, and a semicircular recess, a stiffening-plate for the joint of each bar or rail overlapping the shutting ends of the bar or rail sections on each side of the joint, depending pins or pivots for each stiffening-plate, one pin or pivot at each end of the plate, the pins or pivots furnishing a pivotal connection between the sections of the divided side bar or rail, permitting, in conjunction with the rounded inner corner at the shutting ends of the sections, the edgewise folding of the sections of the divided side bar or rail, a cross-brace or stiffening-bar extending from side bar or rail to side bar or rail and crossing the bars or rails at the joints on the opposite side of each bar or rail to the stiffening-plate, clamping-bolts one for each end of the cross-brace or stiffening-bar passing through the cross-brace or stiffening-bar and the semicircular recesses in the shutting ends of the sections of the side bar or rail and through the stiffening-plate, and tightening-nuts for the clamping-bolts, substantially as described.

4. In a certain-stretcher, the combination of divided side bars or rails edgewise folding each section of each bar or rail at the shutting ends having a rounded inner corner, a stiffening-plate for the joint of each side bar or rail overlapping the shutting ends of the bar or rail sections on each side of the joint and having on each side depending edges or flanges engaging the side faces of the bar or rail, depending pins or pivots at each end of the plate, the pins or pivots furnishing a pivotal connection be-

tween the sections of the divided side bar or rail, permitting, in conjunction with the rounded inner corner at the shutting ends of the sections, the edgewise folding of the sections of the divided bar or rail, a cross-brace or stiffening-bar extending from side bar or rail to side bar or rail and crossing the bars or rails at the joints on the opposite side of each bar or rail to the stiffening-plate, and clamping-bolts, one for each end of the cross-brace or stiffening-bar, passing through the cross-brace or stiffening-bar, between the shutting ends of the sections of the side bar or rail, and through the stiffening-plate, for drawing together the cross-brace or stiffening-bar and the shutting ends of the side bar or rail and forcing the stiffening-plate against the face of the bar or rail on each side of the joint, substantially as described.

5. In a certain-stretcher, the combination of divided side bars or rails edgewise folding each bar or rail at its shutting end having a rounded inner corner, a stiffening-plate for the joint of each bar or rail overlapping the shutting ends of the bar or rail sections on each side of the joint, depending pins or pivots for the stiffening-plate, one pin or pivot at each end of the plate and the pins or pivots of one plate having a greater length than the thickness of the bar or rail and each provided with a stop on its lower end, a cross-brace or stiffening-bar extending from side bar or rail to side bar or rail and crossing the bars or rails at the joints on the opposite face of the bar or rail to the stiffening-plate, clamping-bolts, one for each end of the cross-brace or stiffening-bar, passing through the cross-brace or stiffening-bar between the shutting ends of the sections of the side bar or rail and through the stiffening-plate, one bolt having a greater length than the thickness of the cross-brace or stiffening-bar and the two side bars or rails when folded, tightening-nuts for the clamping-bolts of the cross-brace or stiffening-bar, detachable end bars or rails and removable clamping-bolts for the crossing corners of the side bars or rails and the end bars, or rails for folding the divided side bars or rails edgewise one over the other and on the cross-brace or stiffening-bar and pinning the end bars or rails on the folded sections of the side bars or rails and thereby folding the stretcher, as a whole, in a compact form for shipment and storing away with the retaining-pins protected, substantially as described.

701,015. AUTOMATIC FEED FOR STRAW-BURNING FURNACE. JOHN A. COWAN, Calgary, Canada. Filed Dec. 17, 1900. Serial No. 48,301. (No model.)

Claim.—1. In an automatic feed for straw-burning furnaces, a box or cage for straw and an endless feed-apron suitably carried on a frame pivoted near the bottom and one side of the cage in combination with a suitably-supported transverse conveyor arranged in proximity to the outer side of the lower end of the apron; a feed-box adapted to receive straw from the transverse conveyor; and means for driving the apron and conveyor, substantially as and for the purpose specified.

2. In an automatic feed for straw-burning furnaces, a box or cage for straw and an endless feed-apron suitably carried on a frame pivoted near the bottom and one side of the cage; a cord attached at one end to the mid frame; a guide or pulley on the cage; and a counterbalancing-weight to which the other end of the cord is secured, in combination with a suitably-supported transverse conveyor arranged in proximity to the outer side of the lower end of the apron; a feed-box adapted to receive straw from the transverse conveyor; and means for driving the apron and conveyor, substantially as and for the purpose specified.

3. In an automatic feed for straw-burning furnaces, a box or cage for straw, an endless feed-apron, and a frame carrying and supporting said feed-apron and pivoted near the bottom and one side of the cage, whereby said frame and its endless feed-apron may automatically swing on its pivot and drop to the bottom of the cage as the straw is used up, in combination with means contained in said box or cage for receiving the straw from the apron and conveying it to the furnace, substantially as and for the purpose specified.

4. In an automatic feed for straw-burning furnaces, a box or cage for straw, an endless feed-apron, a frame pivoted near the bottom and one side of said cage and carrying and supporting said feed-apron, a guide or pulley on the cage, a cord connected with the mid frame and passing over said pulley and a counterbalancing-weight connected with the other end of said cord, in combination with means for receiving the straw from the apron and conveying it to the furnace, substantially as and for the purpose specified.

5. In an automatic feed for straw-burning furnaces, the combination of a box or cage for straw, transverse conveying means arranged in communication with the front part of the bottom of the cage, means to move straw in the cage to said conveying means and a feed-box arranged to receive straw from the said conveying means; the said conveying means forcibly pushing the straw in said feed-box, whereby the straw is compressed therein and is fed to the furnace in its compressed condition, substantially as and for the purpose specified.

6. In an automatic feed for straw-burning furnaces, the combination of a box or cage for straw; a transverse curved-toothed conveyor arranged in communication with the bottom part of the cage; means to move straw in the cage to the conveyor; a feed-box arranged to receive straw from the conveyor; and a slotted tongue forming one side of the feed-box and adapted to strip the conveyor, substantially as and for the purpose specified.

7. In an automatic feed for straw-burning furnaces, a box or cage for straw; a transverse curved-toothed conveyor arranged in communication with the bottom part of the cage; means to move straw in the cage to the conveyor; a feed-box arranged to receive straw from the conveyor; and a slotted spring-tongue forming one side of the feed-box and adapted to strip the conveyor, substantially as and for the purpose specified.

8. In an automatic feed for straw-burning furnaces, a box or cage for straw; and an endless feed-apron provided with ribs and teeth inclined to one side, and suitably carried on a frame pivoted near the bottom and one side of the cage in combination with a transverse conveyor arranged in proximity to the outer side of the lower end of the feed-apron; a box adapted to receive straw from the transverse conveyor; and means for driving the apron and the conveyor so that the former delivers straw to the latter and the latter moves in the direction of inclination of the teeth of the apron, substantially as and for the purpose specified.

9. In an automatic feed for straw-burning furnaces, the combination of a box or cage for straw; means to move in the cage to the front part of the bottom of the cage; transverse conveyers arranged in communication with the mid part of the cage and so carried as to draw straw from the mid part of the cage between them; a feed-box adapted to receive straw from the conveyers; means for driving the different parts, substantially as and for the purpose specified.

701,016. ELECTRIC-ARC LAMP. JOHN L. DAVIES, Highbury, England. Filed Jan. 16, 1901. Serial No. 43,574. (No model.)

Claim.—1. The improved means of supporting the regulating-screw consisting of a crown-plate, insulating-spring fixed on the crown-plate, a coil-plate, side rods insulated from the coil-plate, and forcing the coil-plate toward the crown-plate substantially as described.

2. The combination with a grip device controlling the feed or descent of the upper carbon, of means for counterbalancing the upper-carbon holder, consisting of a double pulley, two flexible cords fixed to the

double pulley, the upper-carbon holder and the guided counterweight fixed to the cords substantially as described.

3. The means of suspending the lower-carbon holder and globe consisting of a fixed horizontal plate, insulated side rods pivoted by horizontal pivots to the horizontal plate, a bridge connecting the lower ends of the side rods, a tail-screw screwing in the bridge, a spring-plunger in the bridge, and the carbon-holder and globe-support resting on the plunger substantially as described.

4. The controlling mechanism consisting of the solenoid, solenoid-coils, lever, frame-tube, ring fixed on the frame-tube, screw-rod fixed in the ring and carrying on the fulcrum of the lever, and the coil or spiral springs attached to holes in the lever and connecting the lever to the solenoid-coils substantially as described.

5. The dash-pot arrangement for arc-lamps, consisting of the controlling-lever, the dash-pot cylinder, links connecting the cylinder to the controlling-lever, the lamp-frame, the dash-pot piston pivoted to the frame, and a ball-valve on the top of the dash-pot cylinder substantially as described.

6. The lamp-socket consisting of the crown-plate, a cylindrical casing fixed at its top to the crown-plate, an L-ring fixed to the bottom of the casing, a reflector and removable screw-bottom for fixing the reflector to the ring substantially as described.

701,017. SHAFT-COUPLING. SAMUEL E. DENNEN, Pittsburgh, Pa. Filed July 20, 1901. Serial No. 70,214. (No model.)

Claim.—1. A shaft-coupling having in combination a sectional sleeve, coils arranged within the sleeve, the opposite ends of the coils bearing upon opposite sections and means for drawing the sections toward each other, and thereby reducing the diameter of the coils, substantially as set forth.

2. A shaft-coupling having in combination a sectional sleeve, coils arranged within the sleeve, one end of each coil having a bearing on one of the sleeve-sections, and adjustable bearings for the opposite ends of the coils arranged in the other section, and means for drawing the sections toward each other and thereby reducing the diameter of the coils, substantially as set forth.

701,018. SHAFT-COUPLING. SAMUEL E. DENNEN, Pittsburgh, Pa. Filed Sept. 2, 1901. Serial No. 74,005. (No model.)

Claim.—1. The combination of a case or shell, two gripping-coils arranged within the case or shell, each coil having one end engaging a portion of the case or shell, a lever engaging the other ends of the coils and means for shifting the lever, substantially as set forth.

2. The combination of a case or shell, two gripping-coils arranged within the case or shell, each coil having one end engaging a portion of the case or shell, a floating lever engaging the other ends of the coils and means for shifting the lever, substantially as set forth.

3. The combination of a case or shell, having oppositely-arranged abutments, means for adjusting one of said abutments, two gripping-coils arranged within the case or shell, one end of each coil having a bearing against said abutments, a floating lever engaging the other ends of the coils and means for shifting said lever, substantially as set forth.

4. The combination of a case or shell, two gripping-coils arranged within the case or shell and means for causing both coils to have an equal gripping action, substantially as set forth.

701,019. COUPLING FOR PIPES, &c. SAMUEL R. DIMICK, Pittsburg, Pa. Filed Oct. 21, 1901. Serial No. 79,487. (No model.)

Claim.—1. A coupling for pipes, &c., having in combination two coils externally tapered and threaded and a case or shell internally tapered in opposite directions and threaded to correspond to the threads on the coils, substantially as set forth.

2. A coupling for pipes, &c., having in combination two coils of opposite pitch externally tapered and having external right and left threads and a case or shell internally tapering in opposite directions and internally threaded to correspond with the threads on the coils, substantially as set forth.

3. A coupling for pipes, &c., having in combination two coils of opposite pitch externally tapered, and having external right and left threads, means for locking one end of each coil to the pipe, &c., and a case or shell internally tapering in opposite directions and internally threaded to correspond to the threads on the coils, substantially as set forth.

4. A coupling for pipes, &c., having in combination two coils of opposite pitch externally tapered and having external threads pitched in the same direction as the coils and a case or shell internally tapering in opposite directions and threaded to correspond with the threads on the coils, substantially as set forth.

701,020. COUPLING FOR PIPES, SHAFTS, &c. SAMUEL R. DIMICK, Pittsburg, Pa. Filed Jan. 26, 1902. Serial No. 91,506. (No model.)

Claim.—1. A coupling for pipes, &c., having in combination a sleeve or shell internally tapered in opposite directions and having helically-arranged ribs and two coils externally tapered and having adjacent turns separated to form spaces for the reception of the ribs in the sleeve, substantially as set forth.

2. A coupling for pipes, &c., having in combination a sleeve internally tapered in opposite directions and having helically-arranged ribs, the ribs at one end having a pitch opposite that of the ribs at the other end, and right and left hand coils externally tapered and having adjacent turns separated to form spaces for the reception of the ribs in the sleeve, substantially as set forth.

701,021. CAP-CAPPING MACHINE. MICHAEL DUTY, Rochester, and FRANK GREEN, St. Johnsville, N. Y. Filed June 21, 1901. Serial No. 65,399. (No model.)

Claim.—1. In a cap-capping machine, the combination of a rotary support for the cap to be capped, a rotary crimping-mandrel arranged above said support and adapted to enter the depression of the cap, an upright rock-arm mounted on a horizontal pivot, a stationary support for said pivot, a crimping-roller mounted directly on said rock-arm below the pivot-line thereof to swing with the rock-arm downwardly and inwardly and upwardly and outwardly, and a rotary cam whereby said rock-arm is actuated to swing the crimping-roller downwardly and inwardly against the cap, substantially as set forth.

2. In a cap-capping machine, the combination of a rotary support for the cap to be capped, a rotary crimping-mandrel arranged above said support and adapted to enter the depression of the cap, upright rock-arm mounted on independent horizontal pivots, a stationary support for said pivots, preliminary and final crimping-rollers mounted, respectively, directly on said rock-arm below the pivot-line thereof to swing with the rock-arm downwardly and inwardly and upwardly and outwardly, actuating-arms on said rock-arm, a horizontal rotary shaft arranged between

said actuating-arms, and means on said shaft engaging said actuating-arms and actuating said rollers successively, substantially as set forth.

3. The combination of a crimping-mandrel, a cap-support, a crimping device movable toward and from said mandrel, an actuating device for said crimping device, a frictional driving mechanism for said actuating device, and a releasable stop device whereby said actuating device is held against further action when the crimping operation has been performed, and which is released for again starting said actuating device, substantially as set forth.

4. The combination of a crimping-mandrel, a cap-support, a crimping device movable toward and from said mandrel, a rotary cam for actuating said crimping device, a frictional driving mechanism for actuating said cam, a rotary stop controlling the movement of said cam, and a releasable stop against which said rotary stop engages when the crimping operation has been performed, substantially as set forth.

5. The combination of a crimping-mandrel, a cap-support, which is movable toward and from the same, a crimping device which is movable toward and from the mandrel, an actuating device for said crimping device, a frictional driving mechanism for said actuating device, a releasable stop device connected with the movable cap-support for holding the same in its operative position, and a stop device by which the further action of said actuating device is prevented when the crimping operation has been performed, substantially as set forth.

6. The combination of a crimping-mandrel, a cap-support, which is movable toward and from the same, a crimping device which is movable toward and from said mandrel, a cam for actuating said crimping device, a frictional driving mechanism for said cam, a locking-bar connected with the cam-support, a chipper-cam for releasing the locking-bar, and a stop on said cam for engaging against said bar and holding the actuating-cam against further rotation, substantially as set forth.

7. The combination of a crimping-mandrel, a cap-support which is movable toward and from the same, preliminary and final crimping devices which are movable toward and from said mandrel, a rotary cam-shaft, cam secured to said shaft for actuating said crimping devices, a frictional driving mechanism for said shaft, a locking-bar connected with said cam-support, and a chipper-cam also secured to said shaft and provided with a chipper-flute for releasing said locking-bar and with a stop-flange for engagement against said bar and preventing the further rotation of said cam-shaft, substantially as set forth.

8. The combination of a stationary frame, a crimping-mandrel, a cap-support which is movable in said frame toward and from the mandrel, a locking-bar connected with the cap-support, a stationary stop on said frame against which the locking-bar engages when the support is in its operative position, a crimping device which is movable toward and from said mandrel, and a chipper-cam by which the locking-bar is released from said stop when the crimping operation has been performed, substantially as set forth.

9. The combination of a stationary frame, a crimping-mandrel, a cap-support which is movable in said frame toward and from the mandrel, a locking-bar connected with the cap-support, a stationary stop on said frame against which the locking-bar engages when the support is in its operative position, a crimping-roller which is moved toward and from said mandrel, an actuating-cam for said roller, and a chipper-cam movable with said actuating-cam for releasing said locking-bar from said stop, substantially as set forth.

10. The combination of a crimping-mandrel, a crimping device movable toward and from said mandrel, a cap-support arranged below said mandrel and movable toward and from the same, an upright locking-bar movably connected near its lower end with said cap-support, a handle connected with the lower end of said locking-bar, a stop with which the upper end of said bar engages, and means for automatically releasing said bar from said stop, substantially as set forth.

11. The combination of a crimping-mandrel, a crimping device movable toward and from the same, a horizontal shaft provided with an actuating-cam for said crimping device, a cap-support arranged below said mandrel and movable toward and from the same, an upright driving-shaft, driving connections extending from said shaft to said mandrel and said cap-support, a frictional driving mechanism interposed between said driving-shaft and said cap-support, a locking device for supporting said cap-support in its operative position, and a chipper-cam for releasing said locking device, substantially as set forth.

12. The combination of a crimping-mandrel, a crimping device movable laterally toward and from the mandrel, a cap-support facing the mandrel, a rotary supporting-spindle for the cap-support, a loose connection by which the cap-support is attached to its spindle and which permits of a limited lateral movement of the cap-support on the spindle, and a coupling device by which the cap-support is rotated with the spindle, substantially as set forth.

13. The combination of a cap-support having an internal over-thread, a supporting-spindle which is provided with an external thread which fits loosely in the thread of the support and which is constructed with an upright groove, and a connecting-key which is attached to the support and movable into and out of said groove, substantially as set forth.

701,022. FURNACE. VICTOR E. HOWARD, Worcester, Mass., assignor to the Morgan Construction Company, Worcester, Mass., a Corporation. Filed Jan. 2, 1902. Serial No. 45,008. (No model.)

Claim.—1. In a furnace for heating billets provided with a transverse opening at the charging end of the furnace, of one or more supports for supporting the roof above said opening, one or more doors for closing said opening, with a space between said supports and said doors and an opening in one of the side walls of the furnace in alignment with said space for the introduction of a billet, substantially as described.

2. In a furnace for heating billets having a transverse opening at its charging end, of one or more supports for supporting the roof above said opening, one or more swinging doors for closing said opening, with a space intervening between said doors and said supports for the billet, and an opening in the side wall opposite said space for the introduction of said billet into said intervening space, substantially as described.

3. In a furnace for heating billets having an opening at its charging end transverse to the heating-chamber, supports for supporting the roof above said opening, doors for closing said opening, with an intervening space between said supports and said doors, an opening in one of the side walls of the furnace in alignment with said intervening space for the introduction of a billet, and a side-plate in said intervening space, substantially as described.

4. In a furnace for heating billets provided with a transverse opening in the end wall at the charging end of the furnace, supports for the roof at the charging end of the furnace, said supports extending across said opening, swinging doors for closing said opening, with an intervening space for a billet between said supports and said doors, an opening in one of the side walls of the furnace in alignment with said intervening space for the introduction of a billet, and a pushing mechanism by which the billet is pushed past said doors, substantially as described.

5. In a furnace for heating billets, having an opening in one of its side walls for the introduction of a billet by an endwise movement, of a side-plate in the path of the billet provided with openings for conveyor-rolls, and a series of conveyor-rolls located beneath said side-plate and projecting through said openings by which said billet is moved over said side-plate, substantially as described.

6. In a furnace for heating billets having an opening in one end of its side walls for the introduction of a billet by an endwise movement upon the floor of the furnace, said floor having openings for conveyor-rolls, of conveyor-rolls located in said openings and having their upper surfaces projecting slightly above the floor of the furnace by which said billet is moved over said floor, substantially as described.

7. The combination with a heating-chamber of a furnace, of a side-plate on the plane of the floor of the furnace, an opening in the side wall for the admission of a billet, a pushing mechanism acting through the end of the furnace for pushing the billets lengthwise the heating-chamber, and a swinging door between the heating-chamber and said side-plate, arranged to be raised by the action of the pushing mechanism, substantially as described.

8. The combination with a heating-chamber, of a roof 3, and a plate 5 supporting the end of said roof, upright beams 6 supporting said plate and forming a framework by which the end of said roof is supported, swinging doors hinged to said framework and extending into said heating-chamber to provide an intervening space A between said doors and said beams, means for introducing a billet into said intervening space, and a pushing mechanism for pushing the billet out of said intervening space into the heating-chamber, substantially as described.

701,023. FEEDING MECHANISM FOR BILLET-HEATING FURNACE. VICTOR E. HOWARD and RICHARD E. CARROLL, Worcester, Mass. Filed May 21, 1901. Serial No. 51,080. (No model.)

Claim.—1. The combination with the heating-chamber of a furnace for heating billets and provided with openings in one of its walls for the introduction of feed-rolls, of a series of feed-rolls journaled in bearings outside the heating-chamber and projecting into said chamber with their axes placed at an oblique angle with the wall of the heating-chamber, means for rotating said rolls and an opening for the admission of a billet in alignment with said rolls, substantially as described.

2. In a furnace for heating billets, the combination with a heating-chamber, of a series of feed-rolls arranged in a line parallel with the end wall of the furnace, an opening in the side wall of the furnace for the admission of billets in alignment with said line of rolls, and means for rotating said rolls to move the billets by an endwise motion transversely to the heating-chamber, said rolls having their axes at an oblique angle to said end wall, whereby the billets are crowded against the end wall by the rotation of the rolls, substantially as described.

3. The combination with the chamber of a billet-heating furnace having its end wall provided with a series of openings for the admission of feed-rolls, of feed-rolls having their free ends projecting through said openings into said heating-chamber with the upper surfaces of said rolls slightly raised above the floor of the chamber and a series of reciprocating pushing-bars for pushing the billets over the ends of said rolls upon the floor of the furnace, substantially as described.

4. The combination with the heating-chamber of a furnace having an end wall provided with a series of openings for the admission of feed-rolls into said heating-chamber, of a series of feed-rolls with their free ends inserted through said openings, and plates by which said openings are closed at the rear of said rolls, substantially as described.

5. In a furnace for heating billets, the combination with a heating-chamber having a wall provided with a series of openings for the admission of feed-rolls, of a casting including each of said openings and provided with interior inclined surfaces, a journal-bearing provided with a radial plate wedged between said inclined surfaces, whereby said bearing is held in said casting, a shaft journaled in said bearing and a roll carried by said shaft and projecting through the opening in the furnace-wall into said heating-chamber, substantially as described.

6. The combination with the heating-chamber of a billet-heating furnace having a wall provided with a series of openings for the admission of feed-rolls, of feed-rolls having their free ends projecting through said openings into said heating-chamber, and a series of reciprocating

pushing-bars alternating with said rolls for pushing the billets off the free ends of the rolls upon the floor of the furnace, substantially as described.

7. The combination with the heating-chamber of a billet-heating furnace having openings in its end wall, of a series of rotating shafts journaled outside said chamber, a series of feed-rolls carried by the ends of said shafts and having their free ends projecting through said openings into said chamber, with the body of said rolls cylindrical in shape and having their free ends beveled, and pushing mechanism for pushing the billets off the beveled ends of said rolls upon the floor of the heating-chamber, substantially as described.

8. The combination with the heating-chamber of a billet-heating furnace having a series of openings in its end wall for the admission of a series of feed-rolls, and having an opening in its side wall for the admission of a billet, of a series of conveyors outside the chamber and in alignment with said billet-admission opening, a series of feed-rolls within said chamber and opposite the openings in its end wall and in alignment with said billet-admission opening, and a pushing mechanism by which the billets are pushed off said feed-rolls, substantially as described.

9. The combination with the heating-chamber of a billet-heating furnace having an end wall provided with openings for the insertion of feed-rolls, of a series of feed-rolls inserted in said chamber through said openings with their axes at an oblique angle to said end wall, whereby the billets are carried toward said end wall, and a metal plate supported by the end wall to receive the contact of the billets, substantially as described.

10. The combination with a rotating shaft journaled in bearings and having one end projecting beyond its journal-bearings, of a hollow feed-roll carried upon said journal-bearing and an interior radial flange on the open end of said roll with an annular space between said flange and said journal-bearing for the admission of water into said roll, substantially as described.

11. The combination with the heating-chamber of a billet-heating furnace having openings in its floor for the reception of feed-rolls, of shafts journaled outside said chamber and having their ends projecting into said openings in the floor of the heating-chamber, feed-rolls carried by the projecting ends of said shafts with their upper surfaces slightly raised above the floor of the heating-chamber, means for rotating said shafts and a pushing mechanism by which the billets are pushed off said feed-rolls upon the floor of the heating-chamber, substantially as described.

12. The combination with the heating-chamber of a billet-heating furnace, of a series of feed-rolls inserted in said chamber, means for driving said rolls, an opening in the wall of said chamber in alignment with said rolls, a yielding buffer placed opposite said admission-opening to limit the movement of the billets, and a pushing mechanism for pushing the billets off said rolls upon the floor of the heating-chamber, substantially as described.

701,024. CONVEYER FOR METAL RODS OR BARS. VICTOR E. BEVANS, Worcester, Mass., assignor to the Morgan Construction Company, Worcester, Mass., a Corporation of Massachusetts. Filed Nov. 4, 1891. Serial No. 81,094. (No model.)

Claim.—1. In a conveyor for metal rods or bars, the combination with a series of rotating conveyor-rolls arranged to support a bar thereon, of means whereby the axes of said rolls are shifted into a position on one side of a line at right angles to the line of longitudinal movement of

the bar, whereby a sidewise movement will be imparted to the bar toward one end of the conveyor-rolls, a side wall for limiting the sidewise movement of the bar toward the end of the conveyor-rolls, means whereby the axes of said rolls are shifted from their first position to a position on the opposite side of said right-angled line, whereby a sidewise movement will be imparted to the bar toward the opposite end of the conveyor-rolls, a second side wall for limiting the sidewise movement of the bar toward the opposite end of the conveyor-rolls, and means for preventing the reverse sidewise movement of the bar when the conveyor-rolls are again shifted to their first position, substantially as described.

2. In a conveyor for metal rods or bars, the conveyor-rolls, having means for rotating said rolls and having means for shifting the axes of said rolls from one angle with the line of longitudinal movement of the bar supported on said rolls to another and a different angle, whereby the bar will be moved toward either end of said rolls, means for limiting the sidewise movement of the bar as it is moved toward either end of said rolls, substantially as described.

3. The combination with a series of rotating conveyor-rolls capable of moving a bar longitudinally supported thereon, of means for changing the angle of the axes of the rolls with the line of longitudinal movement of the bar, whereby the bar is moved sidewise toward either end of said conveyor-rolls and side rolls by which the sidewise movement of the bar is limited in either direction, substantially as described.

4. The combination of a series of rotating, central conveyor-rolls having their upper surfaces arranged in the same plane in order to support a bar thereon said rolls having their axes placed obliquely to the line of longitudinal motion of the bar, whereby the bar is moved by a sidewise movement to either the larger or smaller ends of said rolls, said rolls being capable of having their axes shifted in order to reverse the sidewise movement of the bar, substantially as described.

5. The combination with a series of rotating conveyor-rolls for moving a bar longitudinally said rolls having a reduced section at one end forming a step and having their axes capable of being placed at an oblique angle to the line of longitudinal movement of the bar, whereby the bar is moved sidewise toward the reduced end of the conveyor-rolls and over said step, substantially as described.

6. The combination of a series of rotating, central conveyor-rolls having their small ends reduced in diameter forming steps, means whereby said rolls are shifted in position to bring their axes obliquely to line of longitudinal movement of a bar on said conveyor-rolls, whereby a bar is moved sidewise upon the reduced ends of said rolls, means for limiting the sidewise movement of said bar, a series of confining wings placed obliquely to their axes of oscillation and beneath a bar held on the reduced ends of said conveyor-rolls, and means for oscillating said wings, whereby a bar is lifted off said rolls, substantially as described.

7. In a rod or bar conveyor on endless driving-cable, a series of central rolls provided with grooves at their large ends with said grooved ends resting upon said driving-cable, oblique spindles attached to said central rolls rotating in sockets and capable of a rising-and-falling movement therein said sockets being held in vertically adjustable sleeves means for adjusting said sleeves and carrier-rolls by which said driving-cable is supported beneath said conveyor-rolls said rolls being capable of a horizontal, sidewise adjustment, substantially as described.

8. In a rod or bar conveyor the combination of a series of conveyor-rolls, a driving-cable beneath and supporting said rolls and carrier-rolls beneath and supporting said cable said conveyor-rolls being placed contiguous to said carrier-rolls, whereby said conveyor-rolls are maintained in substantially the same horizontal plane and are also allowed a slight yielding motion, substantially as described.

9. The combination with a series of conveyor-rolls of a series of oscillating inclined chills, wings projecting obliquely from the ends of said chills and normally beneath a bar or rod held on said conveyor-rolls and means for oscillating said chills in order to lift a bar off said rolls by the oscillating movement of said wings, substantially as described.

10. The combination with a series of conveyor-rolls, of a series of inclined chills journaled to bearings, wings projecting from the ends of said chills and obliquely thereon, said wings lying normally beneath a bar or rod supported on said conveyor-rolls, means for oscillating said wings having inclined bar-supporting surfaces when raised over which a bar is moved by gravity upon said inclined chills, substantially as described.

11. The combination in a rod or bar conveying mechanism, of a series of inclined chills journaled in bearings and having a series of arms projecting therefrom on opposite sides of said chills and arranged in horizontal rows, with the horizontal rows on one side of said chills alternating with the rows on the opposite side of the chills, with the upper sides of said arms forming steps for a bar in its downward movement by gravity over said inclined chills and the lower sides of said arms forming oblique angles to the chills and oscillating surfaces of greater inclination than the inclination of the chills, whereby an accelerated, sidewise movement is imparted

to a bar in its movement from one row of arms to another, and means for oscillating said chills, substantially as described.

12. The combination with a series of inclined chills and means for oscillating said chills, of a series of arms projecting from said chills and provided with inclined sides arranged to be brought beneath a bar as it is moved by gravity downwardly over said chills and to raise the bar by the oscillation of the chills, whereby an initial impulse is given to the bar at each series of arms, substantially as described.

13. The combination with a series of conveyor-rolls of a series of oscillating wings, said wings being placed obliquely to their axis of oscillation and held normally beneath a bar or rod supported on said conveyor-rolls and means for oscillating said wings, whereby a bar or rod is lifted off said conveyor-rolls, substantially as described.

701,025. GAS-BURNER. WILLIAM BLANDINE, Memphis, Tenn. Filed Aug. 31, 1891. Serial No. 74,817. (No model.)

Claim.—1. In a gas-burner for use with a mantle, the combination with a gas-supply pipe, an air-receiving chamber mounted thereon and means of regulating the supply of air admitted to said chamber, of an enlarged mixing-chamber, a reducing-cap closing same, a central nozzle extended upward from said cap, a burner-cap closing said nozzle having a single central hole and a gaseous disk supporting a baffle-plate in proximity to said hole, substantially as shown and described.

2. In a gas-burner for use with a mantle, the combination with a gas-supply pipe, a perforated disk over the end of said pipe, an air-receiving chamber mounted on said pipe and means of regulating the supply of air admitted to said chamber, of an enlarged mixing-chamber a reducing-cap closing same, a central nozzle of reduced diameter extending upward from said cap, a burner-cap closing said nozzle having a single central hole and a gaseous disk supporting a baffle-plate below said hole, all substantially as shown and described.

3. In a gas-burner, the combination with a gas-supply pipe, an air-receiving chamber mounted thereon, means of regulating the supply of air admitted to said chamber, a mixing-chamber above said air-receiving chamber and a discharge-nozzle, of a burner-cap closing the upper end of said nozzle, a single central hole through said cap a gaseous disk below said cap and a baffle-plate slightly larger than said hole held by said gaseous disk in close proximity to said hole, substantially as shown and described.

4. In a gas-burner, the combination with a gas-supply pipe, a perforated disk over the end of said pipe, an air-receiving chamber mounted on said pipe, air-inlet holes near the bottom and top of said chamber, a mixing-chamber above said air-inlet holes, a reducing-cap closing said chamber, and a short nozzle extending upward therefrom, of a burner-cap closing the upper end of said nozzle, a single central hole through said cap, a gaseous disk below said cap and a baffle-plate slightly larger than said hole held by said gaseous disk in close proximity to said cap, substantially as shown and described.

5. In a gas-burner, the combination with a gas-supply pipe, an air-receiving chamber mounted on said pipe, air-inlet holes near the bottom and top of said chamber, means of regulating the supply of air admitted

through said holes, an enlarged mixing-chamber above said air-inlet holes, a reducing-cap closing said chamber and a short nozzle extending upward therefrom, of a cap closing the upper end of said nozzle, a single central hole through said cap, a gaseous disk below said cap, a baffle-plate slightly larger than said hole, held by said gaseous disk in close proximity to same, substantially as shown and described.

701,026. HYDROCARBON-BURNER. GEORGE E. BLADY, Boston, Mass. Filed Aug. 30, 1891. Serial No. 72,884. (No model.)

Claim.—1. In a burner, the combination with the vapor-generator, of the mixing-chamber having an adjustable ignition-opening, and means, operated by the variations of pressure within the vapor-generator, to automatically proportion the extent of ignition-opening to said pressure, substantially as described.

2. In a burner, the combination with the vapor-generator, of the mixing-chamber receiving the vapor from the generator and provided with an adjustable ignition-opening, a vapor-receiver connected with said generator and means connected with said receiver to automatically adjust the extent of ignition-opening to accord with the vapor-pressure within said receiver and generator, substantially as described.

3. In a burner, the combination with the vapor-generator, of the mixing-chamber having an adjustable ignition-opening, an expandable vapor-receiver connected with said generator, and a rod reciprocated by said expandable receiver and constructed to open and close said ignition-opening, substantially as described.

4. In a burner, the combination with the vapor-generator, of the mixing-chamber receiving vapor from said generator and having a circular ignition-opening, a circular deflector therefor having a threaded stem turning in correspondingly-threaded bearings, an expandable vapor-receiver connected with the vapor-generator, and a rod reciprocated by said expandable receiver and constructed to rotate said stem and thereby raise and lower the deflector in accordance with the pressure within the generator, substantially as described.

5. In a burner, the combination with the vapor-generator, of the mixing-chamber receiving vapor from said generator and having a circular ignition-opening, a circular deflector therefor having a threaded stem turning in correspondingly-threaded bearings, a piston rigid with said stem, an expandable vapor-receiver connected with said generator, a rod reciprocated by said receiver and having a rock-bar meshing with said piston, and a spring acting on said plunger against the vapor-pressure within it, substantially as described.

6. In a burner, the combination with the vapor-generator, of the mixing-chamber receiving vapor from said generator and having an adjustable ignition-opening, a vapor-receiving cylinder connected with said generator, a plunger within the cylinder constructed when reciprocated to open and close said ignition-opening, a helical spring acting against said plunger, and a threaded shoulder for said spring turning in a correspondingly-threaded fixed support, substantially as described.

7. In a burner, the combination with the vapor-generator, of the mixing-chamber receiving vapor from said generator and having a circular ignition-opening, a circular deflector therefor having a threaded stem turning in correspondingly-threaded bearings, a piston rigid with said stem, a cylinder receiving vapor from said generator, a plunger fitting in said cylinder and having a rock-bar meshing with said piston, an externally-threaded shoulder, a helical spring between said spring and plunger-head, and a fixed internally-threaded support for said shoulder, said shoulder being centrally apertured to receive and support the stem of said plunger, substantially as described.

8. In a burner, the combination with the mixing-chamber, of the deflector fixed to the ignition-opening thereof and movable into contact therewith, the contacting surface of said deflector being formed with outwardly-opening grooves, substantially as described.

701,027. PENCIL-SHARPENER. JAMES H. FARMER, Boston, and JOHN E. WARREN, Greenfield, N. H. Filed Apr. 4, 1901. Serial No. 64,378. (No model.)

Claim.—1. A pencil-sharpener comprising a supporting-frame, mechanism for holding the pencil, a rotary cutter-plate having two-edged knives projecting radially therefrom and adapted to make a drawing cut along the pencil, said cutter-plate being detachably and reversibly secured to a shaft, and mechanism for rotating the cutter-plate.

2. A pencil-sharpener comprising a supporting-frame, mechanism for holding the pencil, a rotary cutter-plate having two-edged knives projecting radially therefrom, said cutter-plate being detachably and reversibly secured to its shaft, and mechanism for rotating the cutter-plate.

3. A pencil-sharpener comprising a supporting-frame, mechanism for holding the pencil, a rotary cutter-plate having knives projecting radially therefrom, members with file-surfaces between said knives, and means for rotating the cutter-plate.

4. A pencil-sharpener comprising a supporting-frame; mechanism for holding the pencil; a rotary cutter-plate having knives projecting radially therefrom and adapted to make a drawing cut along the pencil; members with file-surfaces between said knives; and means for rotating the cutter-plate.

5. A pencil-sharpener comprising a supporting-frame; a pinion; a cutter-plate secured to the shaft of said pinion; a driving-gear that meshes with said pinion; said gear having a shaft; a standard; a rotary pencil-holder in said standard; and a pair of intermeshing bevel-gears, one fast upon the shaft of said driving-gear and the other fast to said rotary pencil-holder.

6. In a pencil-sharpener, a device for holding the pencil comprising a spring-metal sleeve having a yielding annular projection on its interior for securing the pencil near one end, and having its other end tapered and slitted and provided with screw-threads on its exterior, and a locking-nut which screws said screw-threads and to secure the pencil at said end.

7. In a pencil-sharpener, the combination of a supporting-frame; a driving-shaft rotatively mounted therein; a cutter provided with radially-projecting arms sharpened at both their edges and reversibly mounted on said driving-shaft; means for detachably securing said cutter to said driving-shaft; a pencil-holder mounted on said supporting-frame; and means for revolving a pencil in cutting contact with said cutter.

701,028. MOTOR-PEDAL. WILLIAM E. FARMER, Chicago, Ill. Filed Mar. 7, 1900. Serial No. 673,970. (No model.)

Claim.—1. The combination with a grooved supporting-spindle the groove of which is constructed to confine bearing-balls from endwise movement of the spindle, of a tubular body surrounding the spindle and provided with a cylindrical inner surface, bearing-balls in said groove in contact with the inner surface of said tubular body, an annular part having a bearing-shoulder removably secured within said body and adapted for contact with the balls to hold the tubular body from endwise movement relatively to the spindle.

2. The combination with a supporting-spindle grooved at each end, the grooves of which are constructed to confine bearing-balls from endwise movement of the spindle, a tubular body surrounding the spindle and having a cylindrical bearing-surface, two sets of bearing-balls inserted in said grooves and bearing against the inner or cylindrical surface of the tubular body, and a sleeve movably secured within the tubular body between the two sets of balls and the ends of which form bearing-shoulders which bear against the balls.

3. A pedal, comprising a supporting-spindle provided with ball-grooves, a tubular body surrounding the spindle and having cylindrical inner surface, bearing-balls inserted in said grooves and bearing against the inner cylindrical surface of the tubular body, and a sleeve movably secured within the tubular body between the two sets of balls and the ends of which form bearing-shoulders to hold the sleeve from endwise movement, said body being provided with holes for the insertion of the balls, which holes are located in position to be covered by the sleeve when the same is secured in place within the tubular body.

4. The combination with a supporting-spindle provided at its ends with ball-grooves constructed to confine the balls from endwise movement of the spindle, a tubular body having a cylindrical inner bearing-surface, bearing-balls inserted in said grooves in contact with said cylindrical bearing-surface, said body being provided with holes for the insertion of the balls within said grooves when the spindle is contained in the body, and means engaging the balls when the parts are assembled to hold the body from endwise movement of the spindle, said means being constructed to close said holes.

5. The combination with a supporting-spindle provided at its ends with ball-grooves constructed to confine the balls from endwise movement of the spindle, balls inserted within said grooves, a tubular body slipped over the spindle having a cylindrical inner bearing-surface with which said balls have contact, a guide-flange at the outer end of the spindle designed to center the spindle in the tubular body when being inserted therein to prevent the escape of balls around the end of the spindle, and means for holding the body from endwise movement of the spindle.

701,029. DEVICE FOR LUBRICATING CAR-JOURNALS. JOHN E. GUN, Franklin, Pa. Filed Aug. 2, 1901. Serial No. 70,758. (No model.)

Claim.—1. The combination with a car-journal, of a journal-box, an oil-reservoir, and means for supporting said reservoir adjacent to the under side of the car-journal, said means comprising a counterweighted lever hinged directly to said reservoir and extending through, and fulcrumed on, one wall of the journal-box, substantially as described.

2. The combination with a car-journal, of a journal-box, an oil-reservoir within said journal-box, and a counterweighted yoke comprising a pair of arms which extend through and are fulcrumed in one wall of the journal-box, the inner ends of said arms being hinged to one end of the oil-reservoir, substantially as described.

3. The combination with a car-journal, of a lubricating-pad, means for yieldingly holding said lubricating-pad against the under surface of the car-journal, oil-receiving means extending laterally from said pad beyond said car-journal, an oil-cup mounted above said pad, and means for supplying oil from said oil-cup directly to said lateral extension, substantially as described.

4. The combination with a car-journal, of a lubricating-pad, means for holding said lubricating-pad yieldingly against the under surface of the car-journal, oil-receiving means extending laterally from said pad beyond said journal, and an oil-cup mounted above said pad, whereby oil may be fed from said oil-cup directly to said oil-receiving means, substantially as described.

5. The combination with a car-journal, of a journal-box, a lubricating-pad within said journal-box, means for yieldingly holding said pad against the under surface of said journal, oil-receiving means extending laterally from said pad beyond said journal, an oil-cup mounted upon said journal-box and means providing a passage leading from said oil-cup to a point within said journal-box, whereby oil may be dropped from said oil-cup directly to said oil-receiving means, substantially as described.

701,030. CAR-AXLE LUBRICATOR. JOHN E. GUN, Franklin, Pa. Filed Aug. 2, 1901. Serial No. 70,759. (No model.)

Claim.—1. The combination with a car-journal, of a journal-box,

an oil-receptacle, means extending laterally through the side of the journal-box for supporting said oil-receptacle, and means for conveying oil from said receptacle to the car-journal, substantially as described.

2. The combination with a car-journal, of a journal-box, an oil-receptacle, means extending laterally through the side of the journal-box for supporting said oil-receptacle adjacent to the car-journal, a lubricating-pad within said oil-receptacle, and means interposed between said pad and the bottom of said oil-receptacle for holding said pad in yielding contact with the car-journal, substantially as described.

3. The combination with a car-journal, of a journal-box, an oil-receptacle, means for supporting said oil-receptacle within said journal-box, said means comprising a supply-pipe extending from said oil-receptacle through the side of said journal-box, a lubricating-pad carried by said oil-receptacle, and means for holding said pad in contact with the car-journal, substantially as described.

4. The combination with a car-journal, of a journal-box, an oil-receptacle, a plurality of supply and supporting pipes extending from said oil-receptacle through one side of said journal-box, a lubricating-pad carried by said oil-receptacle, and means for holding said pad in contact with the car-journal, substantially as described.

701,031. GRINDING-MACHINE. JOHN GLENN, Port Washington, Wis. Filed Sept. 20, 1901. Serial No. 70,914. (No model.)

Claim.—1. A grinding-machine of the species described having the clamp end of its base provided with an inclined plane in the path of the reciprocative grinding-device carrier of the machine.

2. A grinding-machine of the species described having the clamp end of its base provided with inclined planes arranged in the path of the reciprocative grinding-device carrier of the machine to automatically lift the same when so desired in either direction of its travel.

3. A grinding-machine of the species described having the clamp end of its base provided with standards, and converging incline-plane brackets vertically adjustable on the standards in the path of a portion of the reciprocative grinding-device carrier of the machine.

4. A grinding-machine of the species described having the clamp end of its base provided with partially-slotted and flanged standards, converging incline planes having depending apertured cheeks engaging the standards, bolts extending through the standard-slots and cheek-apertures, and nuts run on the bolts, said planes being in the path of a portion of the reciprocative grinding-device carrier of the machine.

5. A grinding-machine of the species described having the clamp end of its base provided with a lateral flange and an upright transverse

rib the upper outer end of which has the form of a vertical leg, and the grinding-device carrier of the machine provided with a lateral leg, the base-rib being for engagement with a lower end recess of a support engageable with the carrier-leg and of itself provided with legs that extend in under said flange, said support serving when in working position to temporarily hold the carrier and grinding device in stationary elevated position.

6. A grinding-machine of the species described provided with an attachment in the form of a support having an upper end seat for a lateral leg on the grinding-device carrier of the machine, a lower recess for the engagement of a base-rib of said machine inside an upper leg extension of the same, and lower end legs that extend under a lateral base-flange of the above-said machine when said engagement is effected, said support in working position serving to hold the carrier and grinding device of the machine in stationary elevated position.

701,032. LIGHTNING-ARRESTER FOR OVERHEAD WIRES. GIOVANNI GOLA, Genoa, Italy. Filed Dec. 10, 1901. Serial No. 66,967. (No model.)

Claim.—1. A lightning-arrester for overhead lines to be inserted in series into the line to be discharged and consisting in a body having an outer surface for much larger than that of the same length of the line to be protected and a protecting-rib along the plane of its greatest section, and consisting earth-conductors.

2. A lightning-arrester for overhead lines to be inserted in series into the line to be discharged, consisting in a hollow body having a very large outer surface and a protecting-rib along the plane of its greatest section, which latter is connected with the part of the overhead wire subjected to atmospheric discharges while its inward surface is connected with the part of the conductor which the apparatus is intended to protect, and earth-conductors arranged to cooperate with said rib.

3. A lightning-arrester for overhead lines to be inserted in series into the line to be discharged consisting in a hollow body of magnetic material, having a very large outer surface which latter is connected with the part of the overhead wire subjected to atmospheric discharges, while its inward surface is connected with the part of the conductor, which the apparatus is intended to protect, a protecting-rib disposed along the plane of greatest section, and earth-conductors arranged to cooperate with said rib.

4. A lightning-arrester for overhead lines to be inserted in series into the line to be discharged having the form of a hollow body whose radii of curvature very much differ between each other, these points where such radii are the smallest facing the earth-conductor, and a zinc frame around the longer radii of said body.

5. A lightning-arrester for overhead lines to be inserted in series into the line to be discharged, having the form of a hollow body, whose inward surface is connected with the part of the circuit to be protected by means of a conductor having a small cross-section and whose direction abruptly changes, combined with a zinc frame on said body, and earth-conductors co-operatively arranged with relation to said frame.

6. A lightning-arrester for overhead lines to be inserted in series into the line to be discharged, surrounded by a magnetic field intended to act on the lines of force of the electricity to be discharged so as to turn them aside from the part of the circuit to be protected, and earth-conductors disposed at the terminus of the larger section of said arrester.

701,033. REIN-HOLDER. JOHN GRANGER, Springfield, N. Mex., assignor to himself and John Rutherford, Springfield, N. Mex. Filed Feb. 21, 1902. Serial No. 64,000. (No model.)

Claim.—1. A rein-holder comprising a shank portion of resilient metal, a clamping-plate extended in opposite directions from the upper end of said shank, and an operating-lever pivoted to the holder and having a cam-surface, substantially as specified.

2. A rein-holder comprising a shank of resilient metal, lateral extensions on said shank for receiving flange-like devices, a clamping-plate extended transversely at the upper end of the shank, an operating-lever having a cam-surface, said operating-lever being pivoted to the holder, and a wear-plate with which said cam-surface may engage, substantially as specified.

3. A run-holder comprising a shank portion of resilient metal, means for securing the same to a dashboard, a clamping-plate extended transversely at the free end of said shank, a lever pivoted to the shank and having a cam portion extended through an opening in said shank, and finger-pieces on opposite sides of said lever, substantially as specified.

701,084. METAL ARCH. RICHARD GRAY, Bloomington, Ill. Filed Jan. 2, 1902. Serial No. 53,246. (No model.)

Claim.—1. An arch made up of metallic plates adjustably connected with each other and bound together with flexible metallic bands.

2. An arch made up of metallic plates, adjustably connected at their inner faces, and bound together with twisted metallic bands at or near their outer faces.

3. The hinge connection between the plates of a metal arch at their edges comprising the head *k*; the undermost end of flange *a*; and the cover *m* with the enlargement *n* upon its upper surface; substantially as described.

4. A metal plate, adapted to join other metal plates in an arch, so as to form an adjustable connection with them, and having transverse flanges with projections or notches adapted to receive and retain flexible bands.

5. In an arch made up of metallic plates, having transverse flanges; a twisted metallic tie between the ends of said flanges, for the purpose specified.

6. A band, comprising two or more strands of flexible metal applied to the members of a metal arch, and means for twisting said strands together.

7. As a part of a metal arch a foundation-piece, having members attached thereto adapted to receive and retain the ends of flexible metallic bands, in combination with flexible metallic bands.

701,085. STEAM-TRAP. JOHN H. HARRIS, Oldham, and THOMAS SPOONER, East Dulwich, England. Filed Sept. 12, 1901. Serial No. 73,571. (No model.)

Claim.—1. In a steam-trap of the character described, the combination of an elongated casing or base-support having a valve-box at one end and a guide at the other end; a thermostatic steam and water tube having one end secured to the casing at the valve-box end of the latter and having its other end loosely engaged with the guide at the opposite end of the casing, said tube communicating with the interior of the valve-box; a valve in the latter controlling the outflow of water of condensation; and operating connections between the movable end of the tube and said valve.

2. In a steam-trap of the character described, the combination of a suitable casing having a steam and water passage-way, a thermostatic tube connected at one end with the casing and communicating with the interior passage-way thereof, a valve in the latter controlling the outflow of water of condensation, a valve-actuating member engaged with the free end of the tube and extending to the opposite end thereof, and operating connections between said member and the valve, substantially as described.

3. In a steam-trap of the character described, the combination of a casing or support, a thermostatic steam and water tube, a valve controlling the condensation-outlet, a cam arranged to increase resistance to opening of said valve as said tube expands, and suitable connections between the tube and the cam operating upon the latter to increase cam-pressure on the valve with expansion of the tube, substantially as described.

4. In a steam-trap of the character described, the combination of a casing or support, a thermostatic steam and water tube, a valve controlling the condensation-outlet, a roller-equipped lever coacting with the said tube, and a cam engaged by the roller and coacting with the valve, substantially as described.

5. In a steam-trap of the character described, the combination of a casing or support, a thermostatic steam and water tube having one end fixed and the other end free, a valve in the casing controlling the condensation-outlet, a lever engaged with the valve and compounded with a cam at the fixed end of the tube, said cam engaged with the valve, and connections between the said lever and the free end of the tube.

6. In a steam-trap the combination of a support or casing comprising a valve-box and having a steam and water passage-way leading thereinto, a thermostatic steam and water tube secured at one end to a part of said casing and slidingly engaged at the other end with another part of the casing, said tube communicating with the passage-way therein, a valve in the valve-box of the casing controlling outflow of water of condensation, and suitable connections between the free end of the tube and said valve, substantially as and for the purpose described.

7. In a steam-trap in combination a casing having a double water-collecting channel or passage therein, a collecting-tube with one end secured thereto a valve casing within the casing, means for transmitting the movement or thrust from the end of the collecting-tube to the valve spindle substantially as described.

701,086. WHEEL-RIM. WALTER S. HARTMAN, Montague, Pa. Filed Mar. 7, 1902. Serial No. 97,153. (No model.)

Claim.—The combination with a rim having a wide groove in its periphery and a narrow groove in the bottom of said wide groove, which narrow groove is connected to an oil-dust, of an absorbent strip mounted in said groove, substantially as described.

701,087. CONCREMENT. THOMAS J. REALE, Baltimore, Md. Filed Dec. 31, 1901. Serial No. 54,745. (No specimens.)

Claim.—1. The new article of manufacture herein described consisting of a union of finely-divided uncooked culms with flour, and the mass dried and reduced to a powdered state for the purpose set forth.

2. A powdered condiment for table and culinary use composed of uncooked culms and flour, substantially as described.

3. A condiment for table and culinary use, composed of uncooked culms and flour, the two substances being thoroughly incorporated, dried and reduced to powder, substantially as and for the purpose set forth.

701,088. FEEDER. GEORGE H. HILGREN, Chicago, Ill. Filed Nov. 13, 1901. Serial No. 52,599. (No model.)

Claim.—1. A feeder for feeding a liquid compound into the feed-water of a boiler, comprising a reservoir for containing the liquid compound, a pipe carrying the reservoir and opening into the feed-water below the water-level, a wash-out valve in the said pipe, a regulating needle-valve having connection with the pipe on opposite sides of the wash-out valve, and an equalizing steam-pipe connected with a steam-supply with the top of the reservoir and with the said pipe below the wash-out valve, as set forth.

2. A feeder for feeding a liquid compound into the feed-water of a boiler, provided with a regulating-valve, comprising a body having a valve-seat, a needle-valve for engaging the said valve-seat, a rod mounted to turn, and carrying on the said needle-valve to move the latter to or from its seat, means for holding the needle-valve against turning, and a funnel leading from the bottom of the said body, as set forth.

3. A feeder for feeding a liquid compound into the feed-water of a boiler, provided with a regulating-valve, comprising a body having a valve-seat, a needle-valve for engaging the said valve-seat, a rod mounted

to turn, and carrying on the said needle-valve to move the latter to or from its seat, means for holding the needle-valve against turning, a funnel leading from the bottom of the said body, and a spring-pressed pin for cleaning the said funnel, as set forth.

4. A feeder for feeding a liquid compound into the feed-water of a boiler, comprising a reservoir for containing the liquid compound, a pipe carrying the reservoir and opening into the feed-water below the water-level, a wash-out valve in the said pipe, an equalizing-pipe connected with a steam-supply, with the top of the said reservoir and with the said pipe below the said wash-out valve, and a regulating-valve comprising a valve-body connected with the said pipe above the wash-out valve, an inlet-valve in the entrance-end of the said valve-body, a funnel in the bottom of the said valve-body, a glass tube connected with the valve-body and into which opens the said funnel, and a fitting carrying the said tube and connected with the said pipe below the wash-out valve, as set forth.

701,089. BAILING-DEVICE. EDWARD W. HILLIARD and HENRY HERRICK, Metropolis, Ill. Filed Jan. 24, 1902. Serial No. 51,105. (No model.)

Claim.—1. In a bailing device, the combination of a packing-box, a plunger, adapted to reciprocate therein, having a bar provided with teeth, a frame, a lever fulcrumed to said frame and connected to said plunger by a cable, and a link pivoted to said lever and adapted to engage said teeth, substantially as set forth.

2. In a bailing device, the combination of a packing-box, a plunger adapted to reciprocate therein, having a bar provided with teeth, a frame, a lever fulcrumed to said frame and connected to said plunger by a cable, a link pivoted to said lever adapted to engage said teeth, and a second link pivoted to said frame and adapted to also engage said teeth, substantially as set forth.

3. In a bailing device, the combination of a packing-box, a plunger adapted to reciprocate therein, having a bar provided with teeth, a frame, a lever fulcrumed to said frame and connected to said plunger by a cable, a link pivoted to said lever and adapted to engage said teeth, and a pin upon said lever adapted to engage said link and release it from the teeth, substantially as set forth.

4. The combination in a bailing device, of a packing-box, a plunger adapted to reciprocate therein, having a bar provided with teeth, a frame, a lever fulcrumed to said frame and connected to said plunger by a cable, a link pivoted to said frame and adapted to also engage said teeth, and a spring connected to said frame and said plunger, substantially as set forth.

701,040. CHICKEN-BROODER. SAMUEL I. HANNEY, Oyster-Land, N. Y. Filed Aug. 17, 1901. Serial No. 72,085. (No model.)

Claim.—A chicken-brooder, comprising a casing, a brooding-chamber therein, cross-pieces *E*, *E'* and *D'* secured to the under surface of the bottom of said casing, a metallic plate secured to the under edge of said strips, and forming the top of a heater-containing compartment having impervious surrounding walls, and communicating passage-ways *F* with the brooding-chamber, a fresh-air chamber with apertures *G* in the wall of the casing, leading thereto, a partition *D* with elongated passage-

way D² cut through its upper portion above said metallic plate, said forcing means of communication between said fresh-air chamber and the heating-space intermediate said plate and the bottom of the breeding-chamber, an open-ended cylindrical shell K mounted in an aperture in the breeding-chamber, a heating-compartment in the upper portion of the casing, a funnel H communicating with the heater-containing compartment and said heating-compartment in the upper portion of the casing, with a passage-way intervening between said funnel and shell, whereby fresh heated air enters the breeding-chamber, as set forth.

701,041. BUTTER-PRINTING APPARATUS. ORRIN A. HOOD, Vinces, Iowa. Filed Sept. 22, 1901. Serial No. 78,951. (No model.)

Claim.—1. In a butter-printing apparatus, the combination of a frame comprising an upper compartment closed on all four sides, open at the top and bottom, with separating cross-wires stretched across said upper compartment, and a lower compartment of larger area, open at one side, a platform fitting said lower compartment, and forming a removable bottom for the upper compartment, a tray adapted to fit at the bottom of the lower compartment when the platform is removed, and a follower fitting the upper compartment, and adapted to press the butter therein down across said wires, and separate the mass into blocks or prints, as described.

2. In a butter-printing apparatus, the herein-described printing-frame, comprising a rectangular box, open at the top and bottom and at the lower vertical half of one side, the upper portion of said box being of smaller area than the lower one so as to provide a ledge against which a removable bottom may bear, and a series of cross-wires stretched across the bottom of the said upper portion, with means substantially as described for fastening one end of each wire to the frame, and for drawing it at the other end.

701,042. TRIPOD. WILLIAM E. HOLMES, Brooklyn, N. Y. Filed June 3, 1901. Serial No. 62,993. (No model.)

Claim.—1. In a tripod, a leg, comprising an upper tubular section and series of lower tubular sections, the sections being arranged to telescope one within the other, the sections below the upper section having each a rib constructed in two members, a space intervening the said members, a sleeve secured interiorly at the bottom of the said sections of the legs with the exception of the lowermost section, each of said sleeves having a slot enlarged at its bottom, forming a shoulder adapted for engagement with the upper portion of the lower rib member of an entering section of the leg, as described.

2. In a tripod, a leg comprising an upper tubular section and series of tubular sections below the upper section, all of the said sections being

adapted to telescope, each section below the upper section having an exterior spring-sleeve at its upper end, and each section below the upper section being provided with an exterior longitudinal rib in two members, said members being separated yet in horizontal alignment, and a sleeve secured to the lower end of each section of the leg with the exception of the bottom section, the said sleeve being at the interior of the said sections and provided with a longitudinal slot comprising a longitudinal member and an enlargement at the lower end of said member, forming a shoulder, the said shoulder in the extended position of the sections of the leg being adapted to engage with the upper ends of the lower members of the ribs of said sections, as described.

3. A tripod, comprising a platform and a plurality of legs, said legs being made of tubes telescoping one within the other, the outer tubes being cylindrical and the inner tubes being provided with longitudinal ribs, all of said tubes excepting the inner one being provided with internal sleeves, and all except the outer one being provided with external sleeves, all of said sleeves being interrupted for the purpose of slidably engaging said ribs.

4. A tripod, comprising a platform, and a plurality of legs, said legs being made of tubes telescoping one within the other, the outer tubes being cylindrical and the inner tubes being provided with longitudinal ribs partially cut away to form jointed members, all of said tubes except the inner one being provided with internal sleeves and all except the outer one being provided with external sleeves, all of said sleeves being interrupted for the purpose of slidably engaging said ribs, said internal sleeves being also cut away to form jointed members mating the jointed members formed by cutting away the longitudinal ribs.

701,043. DRIVING DEVICE FOR SHAPES. JOHANN HOLZMANN, Hildes, Germany, assignor to Aktien-Gesellschaft Schaller Gruben- und Hüttenwerke, Gelsenkirchen, Germany. Filed Oct. 12, 1901. Serial No. 78,448. (No model.)

Claim.—1. A driving device, comprising a shaft, a driver-arm mounted to slide on and to turn with the shaft, friction-rollers journaled on the driver-arm, a revolvable driven wheel concentric with the shaft but independent thereof, and rods on the said wheel and adapted to engage the said friction-rollers, as set forth.

2. A driving device, comprising a shaft, a driver-arm mounted to slide on and to turn with the shaft, friction-rollers journaled on the said driver-arm, a revolvable driven wheel concentric with the shaft but independent thereof, means for driving the said revolvable wheel, and rods on the said wheel and adapted to engage the said friction-rollers to carry the driver-arm along and thereby rotate the shaft until the friction-rollers have the upper ends of the rods, as set forth.

3. A driving device comprising a shaft, a revolvable gear-wheel, an angular shaft extending through said gear-wheel and free to slide endwise,

a pair of longitudinal members rigidly secured upon said gear-wheel and revolvable therewith, a sleeve fixed upon said angular shaft, a pair of rollers connected with said sleeve and free to engage said longitudinal members, and means for actuating said gear-wheel.

701,044. PROCESS OF MAKING PHENYLAMIDOBENZYL-TRIAZOLE. EDUARD KOSCHKE, Frankfurt-on-the-Main, and HERMANN SCHWARZ, Höchst-on-the-Main, Germany, assignors to Farbwerke, vorm. Meister, Lucius & Brüning, Höchst-on-the-Main, Germany, a Corporation of Germany. Filed Oct. 28, 1901. Serial No. 69,086. (No model.)

Claim.—The herein-described process of making phenylamidobenzyl-triazole, which consists in causing glyoxylic-acid chloride to act on aniline base, substantially as set forth.

701,045. METHOD OF MOVING TRAINS. CHARLES W. BROWN, Jersey City, N. J., assignor to himself and Sherwood S. Knapp and Herbert J. Knapp, Brooklyn, N. Y. Filed Feb. 4, 1902. Serial No. 82,028. (No model.)

Claim.—1. A railroad comprising a train-supporting section, a truck-supporting section on a level lower than the train-supporting section, a truck-supporting truck on said lower section, and suitable means carried by said truck for propelling same.

2. A railroad comprising a train-supporting section, a truck-supporting section, and another truck-section for supporting or shifting the first-named truck and train.

3. A railroad comprising train-supporting sections and truck-sections, the latter made to run in different directions and being placed on different levels from one another and from the first-named sections, one of the sections having a truck for supporting a train, and the other sections having a truck for supporting the first-named truck with train.

701,046. MACHINES FOR MARKING OR CUTTING LEATHER. CHARLES W. HOWLAND, Geneva, N. Y., assignor to the Standard Optical Company, a Corporation of New York. Filed Oct. 11, 1901. Serial No. 73,388. (No model.)

Claim.—1. In combination with a rotary support for the article to be cut or marked and having an independent lateral sliding movement, a rotary form synchronized with the rotation of the support and having parallel bearing-surfaces, a cutter or marker engaged with the article and means engaged with said surfaces to move the cutter toward and away from the axis of the form.

2. In combination, a laterally-slidable supporting member for the article to be cut or marked, a cutting or marking member, one of the members being movable relatively to the other to cut or mark the article, a form having parallel surfaces operating to control the position of the cutter on the article, and means to keep the cutting edge of the cutter in a plane tangential to the forming-line of the form.

3. A laterally-slidable support and a cutter or marker for the article to be cut or marked, one of the parts being movable relatively to the other for cutting or marking the article, a form having parallel surfaces operating to control the position of the cutter or marker, said cutter or marker having an independent rocking movement to change the direction of its axis, and means engaging with said surfaces to effect said rocking movement of the cutter or marker for the purpose set forth.

4. In combination with a form and a rotary support for the article to be cut or marked, a cutter or marker, means co-operating with the form to move the cutter relative to the axis of rotation of the support, and means to vary the angle of the axis of the cutter relatively to the surface of the article to be cut or marked for the purpose set forth.

5. A form and a laterally-sliding support for the article to be cut or marked, the form having parallel bearing-surfaces, connections having a universal joint therein to simultaneously rotate said parts, a cutter or marker and additional means engaging with said surfaces to change the position of the axis of one part relatively to the other.

6. A revolvable form and a revolvable support for the article to be cut or marked, means to revolve the parts simultaneously, a cutter or marker, and additional means to move the support relatively to the axis of revolution of the form.

7. In a less cutting or marking machine, a revolvable support for the form, a cutter or marker, and means having parallel surfaces and contact-points engaging therewith to move the support relative to the cutter or marker for the purpose described.

8. A sliding bed, a rotary form-support and a universal shaft connected to rotate the support, in combination with a cutter or marker for the form.

9. In combination, a sliding bed, a cutter or marker, a revolvable support for the article to be cut or marked mounted on the bed, in combination with a universal shaft connected to rotate the support and having one end movable with the sliding bed, and means to rotate the shaft.

10. In a less cutting or marking machine, a form and a laterally-slidable rotary form-support having a graduated center piece to indicate the direction of the major axis of the form, and a cutter or marker for the form controlled by the form.

11. In combination with a rotary form-support, a rotary member connected to rotate with the support, a form detachably mounted on said member, means movable independently of said form and member for holding the form in operative position, and a cutter actuated by the form for the purpose described.

12. In a less cutting or marking machine, a rock-shaft, a cutter-support secured to the rock-shaft and having an independent rocking movement relatively thereto, clamping means for holding the cutter-support in its adjusted position and a rotary form co-operating with means to hold the cutter in a plane tangential to the forming-surface of the form.

13. In combination with a rotary form having parallel forming-surfaces, an oscillating bracket, a rock-shaft mounted on the bracket, a cutter or marker secured to the rock-shaft, and means mounted on the rock-shaft and engaged with the surfaces at this point for oscillating the bracket and rocking the shaft in the bracket.

14. In combination, a rotary form-support, a rotary form, a laterally-sliding form-holder, means to actuate the support and form, a cutter or marker, and means actuated by the form for controlling the position of the cutter.

15. In combination with a rotary form-support, a holder for the less yieldingly mounted to move laterally and endwise for the purpose described.

16. A sliding bed carrying a rotary form-support, a form and a cutter, and driving means for the form suitably connected to the bed to rotate the support.

per at the heel end of the shoe, and means for automatically repressing said hammer.

4. A machine of the character described, comprising fastening mechanism, an abutment for the heel end of the last to rest against, and a hammer in said abutment.

5. A machine of the character described, comprising fastening mechanism, an abutment having a notched face for the heel end of the last to rest against, and a hammer having a head located in the notch when in its operative position.

6. A machine of the character described, comprising fastening mechanism, an abutment for the heel end of the last, a hammer reciprocatory in a plane substantially at right angles to the said heel end of the last, and means for actuating said hammer.

7. A machine of the character described, comprising fastening mechanism, a hammer having a non-yielding flattened end and reciprocatory in a plane substantially at right angles to the heel end of the last, and means for actuating said hammer to cause its end to move laterally toward the sole of the last to lay the upper flat against the center.

8. A machine of the character described, comprising fastening mechanism, a hammer reciprocatory in a plane substantially at right angles to the heel end of the last, means for actuating said hammer, and provisions whereby said hammer may be swung bodily to its operative position.

9. A machine of the character described, comprising fastening mechanism, a hammer reciprocatory in a plane substantially at right angles to the heel end of the last, means for actuating said hammer, and provisions whereby the head of said hammer may be moved at an inclination to said plane.

701,058. BARGE-LOADING DEVICE. WILLIAM L. KILGUSSEY, Cape Girardeau, Mo. Filed Jan. 20, 1902. Serial No. 51,588. (No model.)

Claim.—1. In a barge-loading device, an auxiliary barge comprising a float adapted to be anchored to the shore in combination with a

gang-plank extending from one side thereof to the shore, a platform on the other side adapted to overhang the barge to be loaded, said gang-plank and platform being connected to the barge upon approximately the same level, uprights on opposite ends of the float, respectively, and tension members connecting the tops of said uprights with the outer margin of the platform, substantially as and for the purpose described.

2. In a barge-loading device, an auxiliary barge comprising in combination a float having a deck adapted for the passage of carts and the like thereover, a pair of gang-planks extending laterally from said deck at the ends thereof and adapted to reach the shore, a platform coextensive with and secured to the opposite side of the deck and having its outer margin adapted to overhang the hull of a barge to be loaded, uprights on opposite ends of the deck, respectively, and tension members connecting the tops of said uprights with the outer margin of said platform and the outer ends of said gang-planks, respectively, substantially as and for the purpose described.

3. In a barge-loading device, an auxiliary barge comprising in combination a floating body having a deck adapted for the passage of carts and the like thereover, anchoring devices therefor, a pair of gang-planks extending from the shore side thereof, and a hinged platform on the opposite side of the body the outer margin of which is adapted to overhang the barge to be loaded, substantially as described.

4. In a barge-loading device, an auxiliary barge comprising in combination a floating body having a deck adapted for the passage of carts and the like thereover, a pair of gang-planks extending from the shore side thereof, and a hinged platform on the opposite side of the body the outer margin of which is provided with a continuous upstanding curb and is adapted to overhang the barge to be loaded, substantially as described.

5. In a barge-loading device, the combination with an anchored float having a flat deck, of laterally-extending entrance and exit gang-planks connecting one side of said deck with the shore, and a laterally-extending platform connected with the opposite side of the deck, said platform having a curved outer margin adapted to overhang the hull of the barge to be loaded and further provided with an opening therethrough for the additional discharge of the load to the barge, substantially as and for the purpose described.

6. In a barge-loading device, the combination with a float having a flat deck and lateral extensions therefrom to the shore and over the barge to be loaded, respectively, of weights hung along the sides of the float below the water-line and serving to increase the stability and maintain the equilibrium thereof in the loading operation, substantially as described.

701,054. DOOR CHECK AND CLOSURE. MATTHEW KIMMELER, Oberdorf, Germany. Filed Jan. 28, 1901. Serial No. 44,578. (No model.)

Claim.—1. A door-closing device consisting essentially of a spring having divergent arms, one of which has its free end fitted on a fixed support, and a swinging lever connected with the free end of the other arm of the spring, the said spring having a loose connection with the door.

2. The combination of a supporting-bracket adapted to be secured to a fixed object, a U-shaped lever having one branch pivoted in said bracket, a pin fixedly mounted in said bracket, and a spring loosely connected with the door and having divergent arms, the end of one arm being fitted on the fixed pin and the end of the other arm being fitted on the free branch of the U-shaped lever.

3. The combination of a supporting-bracket adapted to be secured to a fixed object, a lever pivoted in said bracket, a spring adapted to be loosely connected with a swinging object as a door, gate or shutter having divergent arms, one of which has a fixed connection with the bracket and the other of which has its free end fitted on the free end of the lever, and a brake or checking device supported on the bracket and projecting into the path of the lever and the spring-arm connected therewith.

4. The combination of a supporting-bracket adapted to be secured to a fixed object, a lever pivoted thereon, a spring adapted to be loosely connected with a swinging object as a door, gate or shutter having diver-

gent arms, one of which has a fixed connection with the bracket, and the other of which is fitted on the lever, and a checking device adjustably mounted on the bracket and having a tongue depending into the path of the lever and the spring-arm fitted thereon.

5. The combination of a supporting-bracket adapted to be secured to a fixed object, a lever pivoted thereon, a spring adapted to be loosely connected with a swinging object as a door, gate or shutter having divergent arms one of which has a fixed connection with the bracket and the other of which is attached to the end of the lever, a checking device extending into the path of the lever and the attached spring-arm and provided with projections on its upper side, and cut-overs engaging said projections and adapted to move the checking device on the supporting-bracket.

701,055. BOOK-COVER. FRANK C. KIMM, London, and THOMAS R. TOWLER, Woodford, England. Filed Nov. 18, 1901. Serial No. 52,112. (No model.)

Claim.—A book-cover comprising a body of flexible material, a cord extended around and against the edges thereof, an outer cover material secured to the outer surface of the body and having its extended edges turned over the cord and secured to the opposite surface of the body, thus holding the cord in place, and an inner cover material secured to said inner surface of the body and engaging with the overturned or overlapped portion, substantially as specified.

701,056. ATTACHMENT FOR LAMPS. LOUIS F. KIMMEL, Jr., Charleston, S. C. Filed Aug. 22, 1901. Serial No. 73,608. (No model.)

Claim.—1. The combination, with a lamp-burner, of a wick-holder which depends from the said burner and supports the coiled middle part of the wick clear of the oil, said wick-holder being provided with an upwardly-projecting member which holds the lower part of the wick stationary and permits its upper and middle portions to be raised and lowered, substantially as set forth.

2. The combination, with a lamp-burner provided with depending arms, of a wick-holder which engages with the said arms and supports the coiled middle part of the wick clear of the oil, said wick-holder being provided with an upwardly-projecting member which holds the lower part of the wick stationary and permits its upper and middle portions to be raised and lowered, substantially as set forth.

3. The combination, with a lamp-burner provided with a wick-tube, of a hinged gage-plate which projects to a predetermined extent above the top of the said wick-tube when raised, substantially as set forth.

4. The combination, with a lamp-burner provided with depending arms, of a wick-holder engaging with the said arms and supporting the middle part of the wick, said wick-holder being provided with a gage-plate and flange above the gage-plate for holding the bottom end portion of the wick in position, substantially as set forth.

5. The combination, with a lamp-burner provided with depending arms having horizontal portions at their lower ends, of a wick-holder provided with flanges for holding the bottom end portion of the wick in position, a graduated gage-plate below the said flanges, and means for en-

gaging with the horizontal portions of the said arms, substantially as set forth.

6. The combination, with a lamp-burner provided with depending arms, of a wick-holder formed of a strip of metal having its middle portion bent double and provided with notches for engaging with the said arms, said wick-holder being also provided with a gage-plate and means for holding the bottom end portion of the wick against the said gage-plate, substantially as set forth.

701,057. MACHINE FOR TREATING VEGETABLE-STEMS. JEAN A. LACROIX, Paris, France. Filed Mar. 14, 1901. Serial No. 51,109. (No model.)

Claim.—In a machine for treating vegetable-stems, a pair of oppositely-rotating rubbing devices, constructed of radial arms connected by parallel rods, and tubes or sleeves of rather greater internal diameter than the rods, and hanging loosely on the same so as to have a certain internal motion relatively to the rods, substantially as set forth.

701,058. SCUTCHING OR FIBER-PREPARING MACHINE. JEAN A. LACROIX, Paris, France. Filed Mar. 14, 1901. Serial No. 51,110. (No model.)

Claim.—In a stretching or fiber-projecting machine, the combination of a rotary longitudinally-shifting compressor-drum provided with transverse annular grooves, and a compressor-frame arranged above the said drum and pivoted relatively thereto, so as to rest on the drum, said frame being equipped, on the face adjacent the drum, with a plurality of closely-arranged wires, substantially as set forth.

701,059. KEYHOLE-GUARD. LOUIS LAMBERT and ERNEST BERNARD, Geneva, Switzerland. Filed Mar. 4, 1898. Serial No. 94,918. (No model.)

Claim.—1. In keyhole-guards, the combination of a frame or plate having suitable openings and projections forming the fixed portion of the device, with a movable portion or bar intended to be applied upon the said frame or plate and containing suitable levers arranged to engage the said projections of the fixed portion, and with a safety-latch formed of corrugated sheet metal and arranged to disengage the said locking levers from the said studs or projections when it is engaged into the said bar, substantially as and for the purpose specified.

2. In keyhole-guards, the combination of a frame or plate having a suitable opening *a'* and one or more projections *a'* forming the fixed portion of the device, with a movable portion or bar as *b b'* intended to be applied upon the said frame or plate *a* and containing one or more locking levers *c* arranged to engage the said projections or studs *a'* of the plate *a* and with a safety-latch *f* formed of a piece of corrugated sheet metal intended to slide between the corrugated metal pieces *f* and *g* fixed to the bar *b b'*.

701,060. MARINE-ENGINE GOVERNOR. JOHN LEVY and THOMAS SARGENT, London, Canada. Filed Apr. 17, 1901. Serial No. 94,192. (No model.)

Claim.—In a device of the class described, the combination of a valve-chest provided with a suitable part or parts; two valves sliding therein and each adapted to open and close the said ports; a hollow valve-rod secured to one valve; a valve-rod secured to the other and extending

through the hollow valve-rod; an ordinary centrifugal governor connected with one valve-rod; a pendulum adapted to swing relative to the head of the valve in a fore-and-aft plane; and means whereby the relative motion of the pendulum and head when the valve-rod will operate the last-mentioned valve-rod, substantially as described.

701,061. CUTTER. FRANK I. LEVY, Detroit, Mich. Filed Oct. 16, 1901. Serial No. 75,559. (No model.)

Claim.—A cutter, comprising a bar forming a body portion, a handle for the bar, pins mounted loosely on the bar and extending transversely thereof, said pins being of uniform diameter to permit their free adjustment in the bar in direction longitudinally of the axis of pins, and the pins being of length considerably greater than the width of the bar, set-screws working in the bar and respectively engaging the pins adjustably to hold them, and cutting-teeth carried by the lower ends of the pins.

701,062. BASKET. CLAYTON F. LUDWIG, Detroit, Mich. Filed Mar. 2, 1902. Serial No. 94,414. (No model.)

Claim.—1. A basket, having sides formed of upright and spine woven in and out between said uprights and provided with sections in their edges adapted to interlock and prevent the longitudinal movement of said spines, one upon the other.

2. In a basket the combination with a bottom, a top rail consisting of a rectangular frame having recesses in its upper side, and the corresponding, of the sides having their upper ends curved downward and projecting through the recesses of the said rectangular frame, and their lower ends provided with heads to engage the lower face of the bottom, horizontally-arranged spines woven in and out between the said top rail, and having their ends secured to the posts, corner-strips secured to the said posts and covering the ends of the said strips, and tabs on the upper ends of the said top rail, whereby the sides and ends of the basket formed by the separate spines can be tightened independently of each other, substantially as described.

3. In a basket, the combination with a bottom, a top rail consisting of a rectangular frame having recesses in its upper side, and the corresponding, of the sides having their upper ends externally curved downward and projecting through the recesses of the said rectangular frame, and their lower ends provided with heads to engage the lower face of the basket-bottom, a filling for the sides and ends of the basket comprising horizontally-arranged spines woven in and out between the said top rail, certain of said spines provided with extended portions adapted to engage the adjacent strips, the filling constituting the sides being independent of those comprising the ends and having their ends secured to the said posts, corner-strips secured to the said posts and covering the ends of the said strips, and tabs on the upper ends of the said top rail, substantially as described.

701,063. INSULATOR-PIN. FRANK E. LEVY, Victor, N. Y. Filed Mar. 15, 1901. Serial No. 92,459. (No model.)

Claim.—1. An insulator-pin comprising a metallic support having its upper end provided with lugs and an insulating-rod mounted thereon.

2. A pin comprising a metallic support having its central portion enlarged for the purpose of giving lateral support to the pin and having its upper end provided with lugs and an insulating-rod mounted thereon.

3. An insulator-pin comprising a metallic support having its upper

end connected as in or to prevent the rotation of the shackle thereon, said end being provided with lugs and an insulating-rod mounted on said support.

701,064. ROLLING-CHAIR. FRANK HARR, Madison, N. Y., assignor to E. A. Cook & Co., a partnership composed of E. A. Cook, R. J. Rogers, C. A. Brown, and H. W. Childs, Madison, N. Y. Filed Dec. 17, 1901. Serial No. 94,532. (No model.)

Claim.—1. In a device of the character described, for use in connection with a chair employing a hinged back-rest section, the combination with a toothed bracket adapted to be secured to a fixed part of the chair-frame and having tooth-guards arranged above the teeth, the ends of said guards overlapping and being spaced apart, and a latch pivoted in advance of the teeth and in advance of the tooth-guards, of a dog adapted to be pivoted to the back-rest section and to engage the pivoted latch, the tooth-guards, and to disengage into locked engagement with the teeth, substantially as set forth.

2. The combination with a relatively stationary member of an article, and a rotating member connected thereto, of a pawl carried by one of these parts and a ratchet device to be engaged by the pawl carried by the other, the said ratchet device having two ways or tracks for the pawl to move in, one side of one of the ways being provided with a series of teeth, and a separating-partition between the ways which is divided longitudinally to permit the passage of the pawl from one way to the other at a point between the ends of the said partition, and the ways being connected at one end of the partition to permit the pawl to pass around each end from one way to the other, substantially as set forth.

3. The combination with a relatively stationary member of an article, and a movable member connected thereto, of a pawl carried by one of these parts and a ratchet device carried by the other and arranged to be engaged by the pawl, the said ratchet device having two ways or tracks for the pawl to move in, and the ways being separated by a partition intermediate the ends of the partition, and one of the ways being provided with a series of teeth with which the pawl is adapted to engage, substantially as set forth.

4. The combination with a relatively stationary member of an article,

and a movable member connected thereto, of a pawl carried by one of these parts and a ratchet device carried by the other, the said ratchet device having two ways or tracks for the pawl to move in, one of the ways being provided with a series of teeth, a separating-partition between the ways, provided with cross-over-passages from one way to the other, arranged intermediate the ends of the partition, and a latch arranged at one of the ends of the partition and arranged to direct the pawl from one way to the other, substantially as set forth.

701,065. CAR-AXLE BOX AND BEARING. GEORGE W. HARRIS, Brooklyn, N. Y. Filed Feb. 24, 1900. Serial No. 94,099. (No model.)

Claim.—1. In combination with a car-axle box, guiding and supporting ledges in its interior sides, side check-brasses in said ledges and a top beam, substantially as set forth.

2. In combination with a car-axle box, guiding and supporting ledges in its interior sides, side check-brasses in said ledges, and a top beam *D* formed with a head or flange *D'* adapted to retain the side check-brasses, all arranged to curve substantially as herein specified.

3. In combination with a car-axle box, guiding and supporting ledges in its interior sides, side check-brasses in said ledges and a top beam *D* formed with a head or flange *D'* adapted to retain the side check-brasses *E* and with clamping-pieces *G*, all substantially as herein specified.

701,066. PIPE-WRENCH. FREDERICK C. HARTMAN, Houston, Texas. Filed Mar. 12, 1900. Serial No. 94,197. (No model.)

Claim.—1. A pipe-wrench, comprising a longitudinally-slotted male-jaw bar, having transverse projections, a female-slotted movable-jaw portion, having perforations, and a connecting bolt and nut, substantially as specified.

2. In a pipe-wrench, the combination with the arc-grooved and longitudinally-slotted male-jaw bar, of the female-slotted movable-jaw portion having arc-shaped projections, and the connecting bolt and nut, substantially as specified.

3. A pipe-branch having its main bar longitudinally dotted, and provided with a series of transverse arc-shaped slots, a branch-chamber movable-jaw portion having arc-shaped projections, and perforations centered therein, and a connecting hub and nut, substantially as specified.

701,067. MOTOR. JAMES H. MAXWELL, Pittsburg, Pa. Filed Mar. 4, 1908. Serial No. 54,348. (No model.)

Claim.—1. In a motor, the combination of an outer casing having disposed therein partitions, inner casings carried by said partitions, said inner casings forming guideways, the outer casing carrying central shafts having mounted thereon sprocket-wheels, said sprocket-wheels carrying on endless chains, and in turn carrying propellers, substantially as described.

2. In a motor, the combination of an outer casing, having disposed therein partitions, an inner casing carried by said partitions, the said inner casing having suitably mounted therein sprocket-wheels carrying on endless chains and in turn carrying propellers, said propellers having secured to their forward ends arms carrying shafts, said arms being actuated by means of springs, the inner casing having suitable steam-inlets, and the inner and outer casings having suitable steam-outlets, substantially as described.

3. In a motor, the combination of an outer casing carrying partitions, said partitions carrying an inner casing which is formed in a manner as to form a guideway for the propeller, the upper part of said casing being constructed to allow the arms of the propeller to extend outwardly and the lower part of the casing being formed in such a manner as to pass the arms inwardly, allowing the propeller to pass through this constructed portion, the sprocket-wheels carrying suitable recesses for the admission of the propeller to the main pass around their periphery, substantially as described.

701,068. SPRING-CLIP. JAMES H. MAX, Allegheny, Pa. Filed Nov. 12, 1904. Serial No. 51,998. (No model.)

Claim.—A spring-clip comprising a circular metallic band, an outwardly-extending straight portion having a slot formed therein, extending into the circular band, a tongue formed integral with the other end of said circular band corresponding in width to said slot and extending at an angle to said straight portion engaging the outer end of said outwardly-extending straight portion, and an offset formed in said tongue and projecting into the outer end of said slot, substantially as described.

701,069. SPRING-CLIP FOR RING-BANDS. JAMES H. MAX, Allegheny, Pa. Filed Aug. 7, 1904. Serial No. 51,999. (No model.)

Claim.—A spray-pump for explosive-engines, comprising a hollow passage leading to the explosion-chamber, a pair of receptacles disposed adjacent to said passage and connected together by a neck, a piston fitting oil-tight into one of said receptacles and provided with a valve-stem, said valve-stem projecting loosely through said neck into the other receptacle, a valve mounted upon said valve-stem within said other receptacle, a tube connected with said receptacle containing said valve and with said passage leading to the explosion-chamber, said tube being disposed obliquely upward to prevent entry of air-bubbles into said receptacle, a lever for periodically depressing said piston, a cam for actuating said lever, a check-valve for preventing retrogression of the hydrocarbon liquid from said receptacle, and an elevated tank for supplying said liquid under constant pressure to said receptacle.

701,070. BURNING-BOTTLE. JAMES J. MURPHY, Chicago, Ill. Filed Oct. 2, 1901. Serial No. 71,490. (No model.)

Claim.—A burning-bottle, having a cylindrical body laterally rounded to facilitate cleaning, and a conical top having a cylindrical head adapted to receive and to hold the nipple; the said body being provided with an external threaded part and shoulder; the said top being provided with an internal threaded part and flanged shoulder adapted to engage the external threaded part of the said body and to extend slightly over the said external shoulder; and a ring adapted to pass over the external threads and to rest on the shoulder of said body and to be engaged and compressed by the flanged shoulder of the said top, and thus making a secure and tight union of the two parts of said bottle, as and for the purposes specified.

701,071. MARKING-MACHINE. RAYMOND H. MOUNT, Aberdeen, Wash. Filed June 4, 1908. Serial No. 63,698. (No model.)

Claim.—1. In a marking-machine, the combination of a shaft, a type-wheel loosely arranged thereon, a cam carried by the shaft and serving to rotate the wheel to the shaft, means for driving the shaft ground to axis, and taking and impression device working with the wheel.

2. In a marking-machine, the combination with a frame, of a shaft mounted therein to turn around its axis, a type-wheel arranged loosely thereon, a cam mounted on the shaft and serving to rotate the type-wheel to the shaft, means for driving the shaft, and an impression device working with the type-wheel.

3. A marking-machine having a frame, a rotating type-form mounted thereon, a reciprocating bar having connection with the type-form to drive it, an ink device mounted to reciprocate toward and from the type-form, a piston also mounted to reciprocate toward and from the type-form, a reversible drive member, and three cams carried thereon, the same respectively actuating the reciprocating bar, the ink device, and the piston.

4. A marking-machine, having a frame, a rotating type-form, means for imparting movement to the type-form, an ink device, an impression device, a drive-shaft, and three cams on the drive-shaft, said cams respectively operating the means for imparting movement to the type-form, the ink device, and the impression device.

5. The combination with a frame, of a shaft arranged to turn thereon, a type-form on the shaft, a reciprocating bar connected with the shaft to turn it, a spring actuating the bar in one direction, an ink device movable toward and from the type-form, a spring actuating the ink device in one direction, an impression device, a spring actuating the impression device in one direction, and cams for actuating contrary to their springs, the bar, the ink device and the impression device.

701,072. FENCE. JAMES A. H. MOUNT, Leavenworth, Mo. Filed Jan. 28, 1908. Serial No. 61,789. (No model.)

Claim.—A device of the class described comprising a cylindrical casing having a longitudinal slot leading from one end thereof, a screw reversibly engaged with the ends of the casing and having bearings thereon, a shaft having spaced disks thereon, disposed within the casing with its ends engaged with the bearings, a disk and an end closure having each a strap-up loop, a helical spring disposed upon the shaft and having its ends engaged beneath the loops, and a tape attached to the shaft between the loops and passed outwardly through the slot.

701,073. SPEED AND DIRECTION CHANGING MECHANISM. RICHARD L. F. MOON, Paris, France. Filed Feb. 14, 1908. Serial No. 64,388. (No model.)

Claim.—1. A speed and direction changing mechanism for motor-vehicles, comprising a driving-shaft, a driven shaft, a clutch between the two, each clutch when in operation adapted to give the highest speed, type-wheel movable lengthwise on the driving-shaft, a second shaft geared to the driven shaft and spur-gears carried by said second shaft each adapted to gear with one of the lengthwise-movable spur-wheels of the driven shaft to produce varying speeds and a third spur-wheel adapted to mesh with one spur-wheel of each of the two shafts to reverse the speed, substantially as described.

2. A speed and direction changing mechanism for motor-vehicles, comprising a driven shaft, a clutch geared thereto, another shaft J, a number of spur-wheels carried by the latter shaft, which is also geared to the driven shaft, a driving-shaft, a sliding train of gear-wheels carried by the driving-shaft to gear one at a time with a spur-wheel of shaft J or to run free, or to engage with the clutch, according to the degree of lengthwise motion, in combination with a third shaft, a spur-wheel thereon also adapted to be moved lengthwise and adapted to gear with a spur-wheel of the shaft J, and with one on the driving-shaft, substantially as described.

3. A speed and direction changing mechanism for motor-vehicles, comprising a driven shaft, a shaft geared thereto, having spur-gears, a driving-shaft having lengthwise-movable spur-wheels, a third shaft, a lengthwise-movable spur-wheel carried by the third shaft, a casing with a recess in its wall and bearings in the casing carrying said shafts, means for moving the spur-wheel of the third shaft into the recess formed in the casing-wall or into gear with spur-wheels of the other shafts, and means for moving the spur-wheel of the driving-shaft lengthwise, in combination with a clutch mechanism geared to the driven shaft and adapted to clutch the driving-shaft upon its extreme lengthwise movement at which time its spur-wheels are adapted to run free, substantially as described.

701,074. AIR CLEANING AND COOLING DEVICE. JAMES H. MOUNT, Toledo, Ohio. Filed Feb. 3, 1908. Serial No. 64,391. (No model.)

Claim.—The case A having the air and water inlet and outlet, the baffle-plate D having at its lower end the vertical portion d', the backward portion d'' forming the recess, channel or trough and the perforations or holes d''' extending in a line across the bottom of the baffle-plate, as set forth.

701,075. GATHERER OR LIKE INSTRUMENT. RICHARD P. MOUNT, Brooklyn, N. Y. Filed Feb. 12, 1908. Serial No. 64,712. (No model.)

Claim.—1. A surgical instrument of the character described comprising two half-round tubes secured together at their flat sides and forming an inlet-passage extending through the instrument and a return-passage lying adjacent to and to one side of said inlet-passage.

2. In a surgical instrument of the character described, comprising a pair of half-round tubes secured together at their flat sides and forming an inlet-passage and a return-passage lying adjacent to and to one side of said inlet-passage, said inlet-passage having an outlet at the lower end of the instrument and said return-passage having an inlet at the lower end of said instrument.

3. In a surgical instrument of the character described, comprising a pair of half-round tubes secured together at their flat sides and forming an inlet-passage extending through and an opening at the inner end thereof, a return-passage of greater capacity than the inlet-passage said return-passage lying adjacent to but on one side of said inlet-passage, said return-passage having an inlet at the inner end thereof separate from the opening at the inner end of said inlet-passage.

4. A surgical instrument of the character described comprising, a pair of half-round tubes secured together at their flat sides and forming an inlet-passage extending through the instrument, a return-passage lying adjacent thereto and at one side of said inlet-passage, and an outlet adjacent to the inner end of said instrument and leading from said inlet-passage, and an inlet adjacent to the inner end of the instrument and leading into the return-passage.

5. A surgical instrument of the character described comprising, a body portion, a double-walled partition within said body and extending from end to end thereof and dividing the same into two separate passages located side by side, and communication between said passages adjacent to the inner end of the instrument.

6. A surgical instrument of the character described, comprising, a pair of half-round tubes secured together at their flat sides to form a body portion of tubular form, a flat partition extending through said tubular portion and dividing the same into two separate passages one passage affording an inlet for a fluid and the other passage affording a return for a fluid.

701,076. NAIL-HELDER FOR HAMMERS. PATRICK H. McHURRY, Haver, N. J., assignor to William H. Coleman, Haver, N. J. Filed Nov. 21, 1901. Serial No. 65,005. (No model.)

Claim.—1. A device for holding nails to hammer-heads, comprising, a main body or base-plate, a rearwardly-extending member 16 on said body and a holding-arm 17 on said member 16 adapted to be arranged in the receiving-eye of the hammer-head and held between one of the inner surfaces of said eye and a portion of the inserted hammer-handle, for securing said device in position against the hammer-head, the said main body or base-plate being provided with a nail-receiving opening, said opening being wider at the bottom than at its outer edge for retaining a nail in position, substantially as and for the purposes set forth.

2. A device for holding nails to hammer-heads, comprising, a main body or base-plate, a rearwardly-extending member 16 on said body and a holding-arm 17 on said member 16 adapted to be arranged in the receiving-eye of the hammer-head and held between one of the inner surfaces of said eye and a portion of the inserted hammer-handle, for securing said device in position against the hammer-head, the said main body or base-plate being provided with a nail-receiving opening, and a pair of shoulders forming a wide opening for the reception of the head of the nail, substantially as and for the purposes set forth.

3. A device for holding nails to hammer-heads, comprising, a main body or base-plate, a rearwardly-extending member 16 on said main body and a holding-arm 17 on said member 16 adapted to be arranged in the receiving-eye of the hammer-head and held between one of the inner surfaces of said eye and a portion of the inserted hammer-handle, for secur-

ing said device in position against the hammer-head, the said main body being provided with a nail-receiving opening having marginal edges 19 and 20 arranged at different inclinations to each other to provide a wide entrance for the nail and a narrow holding portion at the end of said opening, substantially as and for the purposes set forth.

4. A device for holding nails to hammer-heads, comprising, a main body or base-plate, a rearwardly-extending member 16 on said main body and a holding-arm 17 on said member 16 adapted to be arranged in the receiving-eye of the hammer-head and held between one of the inner surfaces of said eye and a portion of the inserted hammer-handle, for securing said device in position against the hammer-head, the said main body being provided with a nail-receiving opening having marginal edges 19 and 20 arranged at different inclinations to each other to provide a wide entrance for the nail and a narrow holding portion at the end of said opening, and a pair of shoulders forming a wide open portion for the reception of the head of the nail and a narrow open portion in which the shaft of the nail is fitted, substantially as and for the purposes set forth.

5. A device for holding nails to hammer-heads, comprising, a main body or base-plate, means for securing said main body or base-plate in position against a portion of the hammer-head, the said main body being provided with a nail-receiving opening having a pair of marginal edges arranged at different inclinations to each other to provide a wide entrance for the nail and a narrow holding portion at the end of said opening, but the angles of inclination of said marginal edges both being in an upward direction toward the hammer-head, when said nail-holding device is in position against the said hammer-head, whereby the narrow nail-holding portion is lower than the wide receiving-entrance to hold the inserted nail against accidental lateral displacement, substantially as and for the purposes set forth.

6. A device for holding nails to hammer-heads, comprising, a main body or base-plate, means for securing said main body or base-plate in position against a portion of the hammer-head, the said main body being provided with a nail-receiving opening having a pair of marginal edges arranged at different inclinations to each other to provide a wide entrance for the nail and a narrow holding portion at the end of said opening, but the angles of inclination of said marginal edges both being in an upward direction toward the hammer-head, when said nail-holding device is in position against the said hammer-head, whereby the narrow nail-holding portion is lower than the wide receiving-entrance to hold the inserted nail against accidental lateral displacement, and a pair of correspondingly-inclined shoulders forming a wide open portion for the reception of the head of the nail, substantially as and for the purposes set forth.

701,077. STAMP-STEM. WALTER H. McHURRY, Chicago, Ill. Filed Sept. 26, 1901. Serial No. 54,361. (No model.)

Claim.—1. A stem for stamps and analogous drop-hammers consisting of two or more sections adapted to be united in extension of each other, each section being adapted for connection with a hammer or stamp-head and being adapted at its opposite end for engagement with a similar stem-section, whereby said stem-sections may be interchangeably arranged, as and for the purposes set forth.

2. A stem for stamps and analogous drop-hammers comprising two sections united in extension of each other, the upper member being constructed to telescope on the lower member and a cam-surface formed

open the lower end of the telescoping member, as and for the purposes set forth.

3. In combination, a stamp-stem comprising two sections adapted to be united in extension of each other, each comprising an enlarged and conical lower and portion and a tapered upper and portion adapted for engagement with a socket similar to that at its lower end, a cam-surface upon the lower end of each stem-section and a cam or wiper located adjacent to one side of the stamp-stem and immediately below the lower end of the upper stem-section in position to engage the cam-surface thereof.

4. As a new article of manufacture, a stamp-stem section comprising a main body portion provided at one end with an enlargement provided with an inwardly-tapering axially-disposed socket, a transverse drift-aperture intersecting the upper end of said socket, a cam-surface formed at the lower end of said enlargement and a tapered opposite end portion adapted for engagement with a socket substantially similar to that provided in the opposite end of said section.

701,078. AUTOMATIC PAIL. HENRY OTTERMEYER, Baltimore, Md. Filed July 14, 1901. Serial No. 65,006. (No model.)

Claim.—1. An automatic bin, comprising power mechanism, including a driving-pulley; a casing for said mechanism; a standard rising from said casing and provided at its upper end with forwardly-extending brackets; spring-tensioned lifelines journaled in said brackets; a fin-supporting arm pivotally connected at one end to the upper end of said standard above said brackets and lifelines; a fin-shaft mounted in the free end of said arm and provided with fin-blades and a pulley; and an endless band passing around said shaft-pulley, over said tensioned lifelines, and around said driving-pulley, as set forth.

2. An automatic bin, comprising power mechanism, including a driving-pulley; a casing for said mechanism; a standard rising from said casing and provided with a longitudinal rearwardly-opening room, and also provided at its upper end with forwardly-extending brackets and a shoulder, 22', and side arm, 23', above said brackets; a fin-supporting arm pivotally mounted at one end between said arm and provided with a longitudinal strengthening-rib, 25, the said arm, when swung in one direction clamping against said shoulder and supported thereby, and when swung in the other direction, having its web received in said room; spring-tensioned lifelines journaled in said brackets; a fin-shaft mounted in the free end of said supporting-arm and provided with fin-blades and a pulley; and an endless band passing around said shaft-pulley, over said tensioned lifelines, and around said driving-pulley, as set forth.

701,079. ADJUSTABLE SHELF-BRACKET. WILLIAM C. FENNER, Troy, Ohio. Filed Dec. 6, 1901. Serial No. 64,994. (No model.)

Claim.—1. A device of the class described comprising a support, a vertically-adjustable bracket composed of a horizontal bar or lever and an inclined brace pivoted at its upper end to the bar or lever at a point between the ends thereof, and means for detachably interlocking the lower end of the bar or lever and the lower end of the inclined brace with the support and the bar or lever and the lower end of the inclined brace being maintained in interlocking with the support by the weight to which the bracket is subjected, substantially as described.

2. A device of the class described comprising a support, and a bracket composed of an inclined brace and a bar or lever pivoted between its ends to the brace and fulcrumed thereon, said bracket being detachably interlocked with the support, one of the parts being provided with a hooked end and the other part having an opening for the end, substantially as described.

3. A device of the class described comprising a support, and a bracket composed of an inclined brace and a bar or lever fulcrumed between its ends on the brace, said bracket being detachably interlocked with the support by means of studs and openings, one of the parts being provided with studs and the other part having openings composed of enlarged central portions and constricted upper and lower portions, substantially as described.

4. A device of the class described comprising a support, a bracket detachably interlocked with the support and composed of a horizontal bar or lever, and an inclined brace pivoted at its upper end to the bar or lever at a point between the ends thereof, said bar or lever being provided at its lower end with a notch, a shelf supported by the bar or lever, and a fastening device depending from the shelf at one side of the bar or lever and engaging the notch thereof, substantially as described.

5. A device of the class described comprising a support provided with slots, knees connected with the support and designed to be secured to a wall or the like, and a bracket composed of a horizontal bar or lever having a stud detachably interlocked with one of the slots of the support, and an inclined brace pivoted at its upper end to the horizontal bar or lever and provided at its lower end with a stud interlocked with a slot of the support, substantially as described.

701,080. MACHINE FOR TREATING HIDES OR SKINS. FRANKLIN J. PIERCE, Worcester, Mass., assignor to Virginia Machine Company, Boston, Mass., a Corporation of West Virginia. Filed Mar. 7, 1902. Serial No. 67,698. (No model.)

Claim.—1. A machine of the character described, comprising a substantially flat support over the end of which a hide or skin may be folded to its opposite face of the support, an operating-roll normally in the path of movement of the said table or support and adapted to cut upon this portion of the skin which lies on the end of the support without shifting the said skin and for treating the portion of the skin lying on the side of the support, instrumentalities for making the said support and the said roll relatively movable, and means for rotating said roll while the latter is in engagement with the hide or skin.

2. A machine of the character described, comprising a work-support having approximately flat faces and an end, whereby a hide or skin may be doubled over the said end to lie against said faces, and one or more operating-rolls provided with helically-arranged blades or working edges located with relation to said work-support to engage and treat that portion of the hide or skin which is on the end of the support, means for moving one of said parts bodily with relation to the other, means for

holding the said roll in engagement with the hide or skin with a yielding pressure, and means for rotating said roll, substantially as described.

3. A machine of the character described, comprising a movable work-support over which the hide or skin is folded, means for moving said support, a rotatable member provided with helically-arranged working edges located in the path of movement of said support for trussing that portion of the hide or skin which lies on the end of the support and for trussing that portion of the hide or skin lying against the side of the support without shifting the skin and without plating the cheek portions of the skin, and means for operating said roll by power, while it is in engagement with said hide or skin.

4. A machine of the character described, comprising a work-support having two substantially flat faces, whereby a hide or skin may be folded about the end of the support to lie against said flat faces, and means for trussing the entire exposed area of said hide or skin, said means including power-driven rotatable rolls having helically-disposed working edges located with relation to said support to engage and act on the portion of the hide or skin folded about the end of the support, substantially as described.

5. A machine of the character described, comprising a traveling support, rotatable rolls normally intersecting the path of movement of said work-support in different planes at an angle to the path of movement of said support and provided with helically-disposed working edges, said rolls being movable in opposite directions out of the path of movement of said support, and means for rotating said rolls during the movement of the same with relation to the said support, substantially as described.

6. A machine of the character described, comprising a movable work-support over which a hide or skin is adapted to be folded, a rotatable roll having peripheral working edges, pivotally-mounted cranks or arms extending laterally with relation to the path of movement of said work-support and supporting said roll in position to act on the portion of the hide or skin folded over the edge of the work-support, gearing for rotating said roll movable with the cranks or arms, and means for driving said gearing.

7. A machine of the character described, comprising a movable work-support over which a hide or skin is adapted to be folded, means for moving said support, a rotatable working member located in the path of movement of the said support to act on the portion of the hide or skin lying on the edge of the support, pivotally-mounted supports for said rotatable working member, means movable with said pivotally-mounted supports for rotating said working member, and means for engaging said working member with the hide or skin with a yielding pressure.

8. A machine of the character described, comprising a movable work-support over which a hide or skin is adapted to be folded, a rotatable roll provided with helically-arranged working edges, cranks or arms supporting said roll and pivotally mounted to move in the arc of a circle which intersects the path of movement of the work-support, gearing movable with said cranks or arms for rotating said roll, a spring to hold the operating-roll in engagement with the hide or skin with a yielding pressure, a rod on which said spring is placed, and a pivotally-mounted gate for said rod.

9. A machine of the character described, comprising a movable work-support over which a hide or skin is adapted to be folded, main operating cylinders or rolls to act on the sides of the hide or skin, means for rotating said cylinders or rolls, auxiliary operating cylinders or rolls for operating on the portion of the hide or skin lying on the edge or end of the table, supports for said auxiliary cylinders or rolls movable laterally with relation to the path of movement of said work-support, and mechanism for rotating said auxiliary rolls movable with the supports therefor.

10. A machine of the character described, comprising a movable work-support over which the hide or skin is adapted to be folded, a rotatable roll to act on the portion of the hide or skin on the edge or end of the table, pivotally-mounted hubs having cranks or arms which support said roll, mechanism movable with said cranks or arms for rotating said roll, means for holding the said roll in engagement with the hide or skin with a yielding pressure, and means for rotating the movement of the said roll into the path of movement of said work-support.

11. A machine of the character described, comprising a movable work-support over which the hide or skin is adapted to be folded, a rotatable roll to act on the portion of the hide or skin on the edge or end of the table, pivotally-mounted hubs having cranks or arms which support said roll, gearing movable with said cranks or arms for rotating said roll, a second set of cranks, 45, 46, extended from said hubs, a rod pivotally connected with the crank 35, a pivotally-mounted guide into which the free end of said rod is extended, a spring encircling said rod, a dash-pot provided with a piston, and a piston-rod pivotally connected with said piston and with the crank 45.

701,081. SPOOL-MACHINE. HENRY E. FISHER, Lincoln, Mo., assignor to John MacGregor, Lincoln, Mo. Filed Oct. 1, 1901. Serial No. 77,331. (No model.)

Claim.—1. In a spool-machine, the combination of blank-holding mechanism including means for grasping and releasing the blanks, and means for perforating the grouped blanks, mechanism for feeding the blanks singly to the boring mechanism, an inclined runway arranged to receive the bored blanks from the boring mechanism and conduct them by gravitation to a lower point, lath-center offset from the runway, means for transferring the blanks endwise from the lower end of the runway to a point outside the runway, and means for transferring the blanks sideways from said point to a point between the lath-center.

2. In a spool-machine, the combination of a boring mechanism comprising a fixed digging member, an inclined runway having its lower end located below the said fixed member, a vertically-movable digging member arranged to rise above said higher end and in digging a blank, a detent yieldingly held in position to arrest a bored blank in the upper portion of the runway and adapted to be raised with the movable digging member to release said bored blank, a reciprocating bit movable between

the digging member, and mechanism for feeding blanks between the digging member when the movable member is depressed, said blank fed between said members displacing the blank last bored and causing it to be engaged by said detent until the displacement of the detent caused by the upward movement of the movable digging member.

3. In a spool-machine, the combination of a fixed upper digging member internally recessed to form a presser-foot guide, a movable lower digging member, each member being recessed to form jaws, mechanism for reciprocating said movable member, a yielding presser-foot movable in said guide and adapted to bear yieldingly on a blank inserted between the two members and press the same against the jaws of the lower digging member, and a reciprocating bearing-bit movable between the two members.

4. In a spool-machine, the combination of a fixed upper digging member, a movable lower digging member, mechanism for reciprocating said movable member, a yielding presser-foot connected with the fixed member and adapted to bear yieldingly on a blank inserted between the two members, a detent offset to said presser-foot, and a reciprocating bearing-bit movable between the two members.

5. In a spool-machine, the combination of a fixed upper digging member, an inclined primary runway having its lower end located above the lower end of the fixed member and separated from the latter by a vertical space adapted to receive a blank, a secondary inclined runway having its higher end located below the said fixed member, a vertically-movable digging member arranged to rise above said higher end and in digging a blank, a reciprocating bit movable between the digging members, a reciprocating gate adapted to alternately open and close the space between the primary runway and the fixed digging member, a blank-feeding device movable with the said gate and adapted to force a dropped blank forward between the digging members when the movable member is depressed, and inclined tracks at the bottom of said space, adapted to hold the dropped blank against said feeding device by gravitation.

6. In a spool-machine, the combination of a fixed upper digging member, an inclined primary runway having its lower end located above the lower end of the fixed member and separated from the latter by a vertical space adapted to receive a blank, a secondary inclined runway having its higher end located below the said fixed member, a vertically-movable digging member arranged to rise above said higher end and in digging a blank, a reciprocating bit movable between the digging members, a reciprocating gate adapted to alternately open and close the space between the primary runway and the fixed digging member, a blank-feeding device movable with the said gate and adapted to force a dropped blank forward between the digging members when the movable member is depressed, means for raising and depressing the movable digging member, a pivoted lever carrying said gate and feeding device, and connections between the said movable digging member and lever, whereby the gate and feeding device are moved forward to close said space and feed a blank during the depression of the movable digging member and are moved backward to open said space during the ascent of the movable digging member.

7. In a spool-machine, the combination of an inclined runway having a fixed blank-arresting stop at its lower end, means for transferring the lowest blank endwise in a point outside the runway, lath-center offset from the runway, and means for transferring the said blank sideways to a point between the lath-center.

8. In a spool-machine, the combination of an inclined runway having a fixed blank-arresting stop at its lower end, a reciprocating slide having a pin and a pushing-shoulder movable across the runway to transfer the lowest blank endwise in a point outside the runway, lath-center offset from the runway, and means for transferring the blank sideways to a point between said lath-center.

9. In a spool-machine, the combination of an inclined runway having a fixed blank-arresting stop at its lower end, means for transferring the lowest blank endwise in a point outside the runway, lath-center offset from the runway, an oscillating carrier having jaws adapted to grasp the blank at the end of its endwise movement, and to transfer the blank to a point between the lath-center.

10. In a spool-machine, the combination of an inclined runway having a fixed blank-arresting stop at its lower end, means for transferring the lowest blank endwise in a point outside the runway, a fixed stop or abutment arranged to limit the endwise movement of the blank, lath-center offset from the runway, and means for transferring the blank sideways to a point between said center.

11. In a spool-machine, the combination of an inclined runway adapted to receive spool-blanks and having a fixed blank-arresting stop at its lower end, and openings in the lower portions of its sides, a reciprocating transferring device movable through said openings across the runway to move the lowest blank endwise out of the runway, said device comprising a pin and a pushing-shoulder behind the pin, and means outside the runway for grasping the blank at the end of its endwise movement.

12. In a spool-machine, the combination of an inclined runway adapted to receive spool-blanks and having a fixed blank-arresting stop at its lower end and openings in the lower portions of its sides, a transferring device movable through said openings to give the lowest blank an endwise movement out of the runway, said device comprising a pin and a pushing-shoulder behind the pin, a fixed stop or abutment outside the runway to limit the endwise movement of the blank, means for reciprocating said transferring device, said means having provision for giving the transferring device a yielding forward movement, lath-center offset from the runway, and means for transferring the blank sideways to a point between the lath-center.

13. In a spool-machine, the combination of an inclined runway adapted to receive spool-blanks and having a fixed blank-arresting stop at its lower end and openings in the lower portions of its sides, a reciprocating transferring device movable through said openings across the runway to give the lowest blank an endwise movement out of the runway, said device comprising a pin and a pushing-shoulder behind the pin, a yielding stop adapted to arrest the blank while the pin is entering its aperture and adapted to yield to the movement imparted to the blank by said shoulder, means for grasping and holding the blank at a point outside the runway, and a detent adapted to engage the blank after it reaches the end of its endwise movement and prevent it from being moved backward by the transferring device.

14. In a spool-machine, the combination of an inclined runway having a fixed blank-arresting stop at its lower end and a blank-outlet in the lower portion of one of its sides, means for transferring the lowest blank endwise through said outlet, lath-center offset from the runway, an oscillating carrier having jaws adapted to grasp a spool-blank projecting from said outlet, the path of said carrier extending between the lath-center, and the guard or guide-plates 89 and 91 located at opposite sides of said path and having shoulders or tracks 92 arranged to bear on the under side of the transferred blank, one of said plates having a blank-receiving opening in alignment with the blank-outlet of the runway, while the other plate presents a solid blank stop or abutment opposite said opening.

15. In a spool-machine, the combination of a fixed or holder equipped with rotatable turning-blades movable in a substantially horizontal path, lath-center adapted to hold a spool in the path of said blades and to rotate said spool, and an oscillating carrier-arm having blank-grasping jaws at its outer end, said jaws being movable by the oscillatory movement of the carrier-arm in a segmental path which is arranged to give the jaws a substantially vertical movement when they are approaching the lath-center, so that a spool which may have adhered to said center after the turning operation is freed downwardly by the jaws away from the turning-blades.

16. The combination with the lath-centers d and e, and the heads i and j, provided respectively with the knives k and k', of a pusher independently movable in the movable head j and adapted to project from the end thereof, and means for alternately locking and releasing said pusher, said means comprising a lever pivoted to said head j and having an arm projecting therefrom, a slide movable in guides carried by the head j and provided with a recessed upper edge on which said arm bears, and fixed stops arranged to limit the movement of said slide.

701,082. BENDING-MACHINE. CLARA FLEMING, Sylvania, and WILLIAM E. FISHER, Baltimore, Md., assignors to George F. Fisher, deceased. Filed Apr. 29, 1901. Serial No. 69,066. (No model.)

Claim.—1. In a machine for bending metal bars, the combination of a cross-head; means for reciprocating said cross-head; a die-block carried by said cross-head; two slides, one at either side of said cross-head and adapted to follow the ends of the bar; means for reciprocating said slides; brackets, g, provided with cross-roads, f, and also provided with arms, f', depending from said rods and adapted to form guides for the bar; and means for bending the bar around the die-block.

2. In a machine for bending metal bars, the combination of the reciprocating cross-head; the die-block carried thereby; two bell-crank levers each of which is fulcrumed at one side of said cross-head and said levers provided with inwardly-projecting forward ends adapted to be moved outwardly by the forward movement of said cross-head whereby the other ends of said levers are drawn inwardly to bend the bar around the die-block; and a spring-actuated rod secured to each lever forward of its fulcrum-point to restore said levers to the normal position.

3. In a machine for bending metal bars the combination of a cross-head having a crank; a cross-head; a connecting-rod connecting said crank and cross-head whereby the latter is reciprocated; a lever pivoted on said cross-head and reciprocating therewith; a stationary device for depressing the end of said lever; means for bending the metal bars; and means consisting with the pivoted reciprocating lever for guiding said bent bars.

4. In a machine for bending metal bars the combination of a cross-head; means for reciprocating said cross-head; a die-block reciprocated by said cross-head; bell-crank levers pivoted to the frame of the machine for bending a bar around the die-block; means on the cross-head for operating said bell-crank levers; spring-operated rods pivoted to said levers for restoring them to the normal position when the cross-head has been retracted; and means operated by the movement of the cross-head for ejecting the bent bar from the die-block.

5. In a machine for bending metal bars the combination of a cross-head; a lever pivoted to said cross-head and having an inclined forward end; a forked ejector carried by the forward end of said inclined lever; a die-block; means for bending the metal bar around the die-block; and a stationary device adapted to contact with the inclined forward end of said lever when the cross-head is retracted whereby the bent bar will be ejected from the die-block.

6. In a machine for bending metal bars the combination of a cross-head having a crank; a cross-head reciprocated by the crank; a die-block reciprocated by the cross-head; means for bending the bar around the die-block; means for ejecting said bent bar; a wheel revolvable in a horizontal plane and means connecting between the ejector and said wheel for discharging the bent bars onto said revolvable wheel.

7. In a machine for bending metal bars the combination of a cross-head; an ejector; a die-block; means for reciprocating said cross-head and die-block; a wheel revolvable in a horizontal plane beneath said machine and an inclined guide interposed between said wheel and the point of ejecting the bent bars whereby the bent bars after being ejected are guided onto said wheel.

8. In a machine for bending metal bars, the combination with the bent bars provided with a discharge-opening, of means for bending the bar on said base; means whereby the bent bar will drop through said discharge-opening; a wheel mounted to revolve under said base with its rim in registry with said discharge-opening; and an inclined guide interposed between said rim and said discharge-opening and on which guide the bent bars slide from said opening onto said wheel-rim.

701,088. BENDING-MACHINE. OLGA FROST, Olynville, and WILLIAM E. BROWN, Baltimore, Md., administrators of George F. Frost, deceased. Filed Apr. 22, 1901. Serial No. 98,098. (No model.)

Claim.—1. In a press for the purpose described, the combination of two rolls mounted to revolve one above the other and the lower roll being vertically adjustable; a cross-head; means for reciprocating said cross-head; a die-holder pivotally connected at one end to said cross-head, with its other end supported on said lower roll; and a die-block carried by said die-holder, as set forth.

2. In a press for the purpose described, the combination of the standards, each provided with an upper and a lower journal-box, the lower boxes being provided with inclined bottom walls; a wedge beneath the inclined bottom wall of each lower box and said wedges provided with means whereby they may be moved to raise and lower the lower journal-boxes; two rolls mounted one above the other in said journal-boxes; a die mounted in the upper roll; a cross-head; a die-holder pivotally con-

nected at one end to said cross-head, with its other end supported on said lower roll; and a die-block carried to the free end of said die-holder, as set forth.

3. The combination of the standards; an upper die-roll revolvable on a shaft between said standards; a driving-gear mounted on said shaft; a second roll beneath said die-roll; a main shaft extending crosswise of the machine and carrying a pinion which meshes with the gear on the upper die-roll shaft; a die-block adapted to be reciprocated between said rolls; an endless-belt conveyor traveling in front of said rolls and means connecting between the main shaft and conveyor for driving the latter.

4. The combination of the standards; an upper die-roll mounted on a shaft between said standards; a gear-wheel mounted on said shaft; a second roll mounted beneath said die-roll and between said standards; a die-block adapted to be reciprocated between said rolls; a main driving-shaft extending crosswise of the machine and carrying a pinion which meshes with the gear-wheel on the die-roll shaft; an endless conveyor arranged to travel in front of said rolls; a counter-shaft mounted on the machine and connected with said main shaft as to be turned with the latter, said counter-shaft being provided with a worm; and a worm-gear on one of the conveyor-shafts meshing with said worm, as set forth.

701,084. MECHANISM FOR CLEANING BOTTLES. ANDREW A. FROST, Copenhagen, Denmark. Filed Sept. 28, 1901. Serial No. 77,109. (No model.)

Claim.—Improvement in brushes for cleaning bottles formed of strips of caoutchouc or other suitable material inserted in a spindle, characterized thereby, that the strips are inserted loosely in holes, which are bored obliquely through the spindle and arranged in such a manner that the upper point of each hole is in level with the lowest point of the next hole above, and so on.

701,085. TROLLEY-WHEEL. JAMES FROST, JR., M. Filed Jan. 29, 1902. Serial No. 21,728. (No model.)

Claim.—The combination with a trolley-wheel, of a hub having hinged arms, a stem rigid with one of said arms, a sliding tapered sleeve

on the stem engaging the arm to clamp the wheel therebetween, and a jaw-set on the stem binding the sleeve.

701,086. CLOSURE. CHARLES FROST, Detroit, Mich., assignor, by mesne assignments, to Briggs Manufacturing Company, Detroit, Mich., a Corporation. Filed Sept. 6, 1901. Serial No. 74,691. (No model.)

Claim.—1. The combination of a receptacle cover or top having a fill and a discharge opening therein, closures for said openings, a fixed support rigidly attached to and depending from the cover, a spring-carrier for both closures mounted upon the support in proximity to said cover for horizontal rotation, and means for actuating the carrier.

2. The combination of a receptacle cover or top having a fill and a discharge opening therein, closures for said openings, a support rigidly attached to and depending centrally from the cover, a spring-carrier for both closures overlaid upon the support for horizontal movement, and an actuating device for the carrier rigidly secured to the closure controlling the fill-opening.

3. The combination of a can cover or top having a discharge and a fill opening therein, the portions of the cover about the openings being struck up to form outwardly-extending annular flanges, a carrier-plate formed of spring metal pivoted centrally to the can-cover for horizontal rotation, raised caps at the ends of said integral with the carrier-plate, and a stud fixed upon the cap controlling the fill-opening and projecting through said opening, substantially as described.

4. The combination of a receptacle cover or top having a fill and a discharge opening formed therein, a single carrier-plate formed of spring metal pivoted centrally to and upon the under side of said cover or top for horizontal rotation, raised caps upon the plate ends adapted to be projected upwardly by the plate when rotated within said openings, and bearing normally against the under face of the cover or top when out of registration with the openings, and a stud upon one of the caps for rotating the carrier.

701,087. THILL-COUPPLER. RALPH E. SAFF, Worcester, Pa. Filed Feb. 8, 1902. Serial No. 22,598. (No model.)

Claim.—1. In a thill-coupling, the combination of the shaft, the coupling-bar for securing said shaft to the axle, means for connecting the same, clips carried by the shaft, a thill-eye held therein, means for connecting these parts, a yoke-piece having arms for holding the connecting means of the thill-eye in place, means for combining the thill-eye arranged between the latter and the yoke-piece, and an arm carried by the coupling-bar in which said yoke-piece is pivoted, said arm extending from the center of said coupling-bar and curved as to engage the yoke-piece in proper position, such construction permitting the use of an ordinary shaft with its usual hole and centering means.

2. The combination in a thill-coupling of the character described, of the shaft having clips carrying the thill-eye, a coupling-bar having a projecting arm, a yoke-piece pivoted to the projecting arm of the coupling-bar and having side arms to retain the coupling-plate in place, said yoke-piece having a depression between its side arms, a rubber pad for the thill-eye, and a bar for carrying said pad, said bar having a depression in the

rear fitting the coupling-bar, and a projection in the bottom which fits the depression in the yoke-piece, all of said parts coacting and serving to position the bar carrying the pad with relation to the thill-eye.

3. The combination in a thill-coupling, of the shaft, a thill-eye secured therein, a rubber pad carried by the shaft, said shaft having a projecting portion, an inclining and supporting cup for said pad, said cup being recessed at the rear for the reception of the projecting portion of the shaft whereby the latter serves to position said cup, and a loose spring-plate interposed between said pad and the thill-eye, said plate having projections at the front and rear which extend over and engage the cup carrying the rubber pad, the cup being recessed at the rear to receive the rear projection of the plate.

4. In a thill-coupling, the combination of a rubber pad to combine the thill-eye, a cup or box in which said pad is mounted, an arched spring-plate carried in said cup beneath the pad, and means for adjusting said spring-plate from one side of the cup.

5. The combination in a thill-coupling, of the shaft, the thill-eye secured therein, a coupling-bar, a yoke-piece carried by said bar, a rubber pad interposed between said yoke-piece and the thill-eye, a bar carrying said pad, an arched spring-plate in said bar supporting the pad, and an adjusting-screw tapped into said bar and set so as to act upon one side of the spring-plate to cause the latter to raise the pad at the rear.

701,088. MECHANICAL MOVEMENT. ALBERT H. RAY, Ashland, Mass. Filed Aug. 11, 1900. Serial No. 24,398. (No model.)

Claim.—1. A mechanical movement comprising two concentric and directionally-movable elements one within the other, one driving and the other driven, and automatic radially-movable clutch mechanism interposed between said elements, whereby the one element is positively intermittently rotated at a speed equal to that of the other, and permitted to rest, alternately.

2. A mechanical movement comprising two unidirectionally-movable concentric elements one within the other, one driving and the other driven, and automatic radially-movable mechanism interposed between said elements, whereby during a continued rotation of the driving element, the driven element is for alternate periods of time, successively positively rotated and permitted to rest.

3. A mechanical movement comprising two unidirectionally-movable concentric elements one within the other, one driving and the other driven, a positive radially-movable clutch member, and a cam for automatically causing the rotation of said clutch member whereby during continued rotation of the driving element, the driven element is for alternate predetermined periods of time, rotated and permitted to rest.

4. A mechanical movement comprising two unidirectionally-movable concentric elements one within the other, one driving and the other driven, a radially-movable spring-pressed positive clutch member rotatable with the driving element and adapted to successively engage engaging portions of the driven element, and a stationary cam for causing the rotation of said clutch member; whereby during continued rotation of the driving element, the driven element is for alternate predetermined periods of time rotated and permitted to rest.

5. A mechanical movement comprising a driving-shaft, a driven wheel thereon having internal notches, a stationary cam, and a carrier within said wheel and having a radially-movable clutch member controlled by said cam, and adapted to be engaged with and released from the notches in the wheel.

6. A mechanical movement comprising two rotatable members mounted for peripheral cooperation, a driven shaft on which one of said members is mounted, a unidirectionally-rotating driving-shaft for the other member adapted to rotate while the driven shaft is at rest, and intervening power-transmitting mechanism, including coacting gears, whereby the driven shaft is automatically partially rotated by the driving-shaft for predetermined periods of time at a predetermined speed, with predetermined alternating periods of rest.

7. A mechanical movement comprising two rotatable members mounted for peripheral cooperation, a driven shaft on which one of said members is mounted, a driving-shaft rotatable while the driven shaft is at rest, gearing interposed between said shafts, and automatic clutch mechanism, whereby the driven shaft is partially rotated for predetermined periods of time with alternating periods of rest.

8. A mechanical movement comprising two rotatable members mounted for peripheral cooperation, a driven shaft on which one of said members is mounted, a driving-shaft for the other member rotatable while the

driven shaft is at rest, gearing connecting said shaft, a cam, and cam-controlled clutch mechanism between the gearing and one of said shafts, whereby the driven shaft is alternately partially rotated and held at rest.

9. A mechanical movement comprising two rotatable members mounted for peripheral cooperation, a driven shaft on which one of said members is mounted, a driving-shaft for the other member rotatable while the driven shaft is at rest, gearing between said shafts and rigidly connected to one of said shafts, a carrier, an automatic clutch member adapted to intermittently connect the gearing with the other of said shafts, and means for positively disconnecting the clutch upon a partial rotation of the driven shaft.

10. The combination, with a couple of cooperating members mounted for peripheral cooperation, one of which is adapted to remain at rest at intervals during the rotation of the other member; of mechanism for causing the first-mentioned member to partially rotate intermittently in exact peripheral union with the other member, said mechanism including continuously-meshing gears interposed between said members, and an automatic clutch for intermittently connecting the gears with one of said members.

11. The combination, with a couple of cooperating members mounted for peripheral cooperation, one of which is adapted to remain at rest at intervals during the rotation of the other member; of mechanism for causing the first-mentioned member to partially rotate intermittently in exact peripheral union with the other member, continuously-meshing gears interposed between said members, a clutch member interposed between the gears and one of said members, and a cam for automatically controlling said clutch member at regular intervals.

12. The combination, with a couple of cooperating members, one of which is adapted to remain at rest at intervals during the rotation of the other member; of mechanism for causing the first-mentioned member to rotate intermittently in exact peripheral union with the other member, said mechanism including shafts supporting and rotating said members, continuously-meshing gears between said shafts, a clutch member carried by one of said shafts and adapted to intermittently and positively engage the gear thereon, and a stationary cam for automatically controlling said clutch member.

701,089. FLUID-PRESSURE REGULATOR. WALTER H. REAGAN, Peoria, Ill. Filed Mar. 20, 1901. Serial No. 63,392. (No model.)

Claim.—1. The combination of an air-pump, a reciprocating arm adapted to engage the air-pump piston-rod to produce an intake, a catch, a part of which is on said arm and the other part upon said piston-rod, one part of said catch being movable relative to the part upon which it is located, said parts of said catch being adapted to engage each other to secure said reciprocating arm to said piston, and means controlled by the air-pressure adapted to act directly on the said relatively movable part of said catch to disengage it from the other.

2. In combination with an air-pump and its piston, a grooved piston-rod, a hooked spring extending lengthwise in said groove, a reciprocating slide provided with a hook adapted to engage the hooked spring, means for producing reciprocation of the slide, a disengaging device arranged to be actuated by the pressure of air produced by the pump and adapted to disengage the two hooks, substantially as described.

3. In combination with an air-pump and its piston, a spring lying lengthwise the piston-rod, means for reciprocating said piston-rod, a sliding block arranged to engage under the spring and between it and the piston-rod, and to regulate the tension of said spring, substantially as described.

4. In combination with an air-pump and its piston, a spring lying lengthwise the piston-rod, means for reciprocating said piston-rod, a sliding block arranged to engage under the spring and between it and the piston-rod, and to regulate the tension of said spring, and means for holding said block in place, substantially as described.

701,090. DEVICE FOR CENTERING PRINTERS' ROLLERS. HENRY A. REED, Brooklyn, N. Y. Filed Sept. 20, 1901. Serial No. 75,982. (No model.)

Claim.—1. A centering device for printers' rollers having a plurality of members adapted to engage the inner surface of a roll at separate places and yieldable means for exerting a constant pressure against said members to force their working ends against said surface.

2. A centering device for printers' rollers including a centering member and a backing carrying the centering member, means for detachably connecting said parts, and means acting against said centering member to normally increase the effective size thereof.

3. A centering device for printers' rollers including a backing and a ring on the same, said parts being detachably connected, and an adjustable centering member in connection with the backing and ring.

4. A centering device for printers' rollers comprising a backing, spreading-links for centering in a roll and means upon the backing to which said links are connected substantially as described.

5. A centering device comprising a backing, a series of links, and means upon the backing to which said links are connected and a spring made to spread all the links to secure uniform action or wear substantially as described.

6. A backing having a fixed and a slidable ring, a spring coiled about and braced against the backing and made to act on the movable ring, and links joined to one another and to the rings so as to be spread or expanded as the spring presses the rings toward one another substantially as described.

701,091. BELT-CLAMP FOR BUCKLES. LOUIS SAMARA, Brooklyn, N. Y. Filed Apr. 16, 1901. Serial No. 66,905. (No model.)

Claim.—As a new article of manufacture, a belt-clamp for buckles, consisting of an approximately rectangular plate provided at one end with forwardly-projecting spaced hooks for engaging the tongue-bar of the belt-buckle, at the other end with a loop projecting from its front face, through which loop the free end of the belt which is engaged by the buckle is adapted to be passed so as to overlap the clamp, and intermediate of its ends with two spaced slots forming a cross-bar having open front up therefrom and projecting from its front face, the said slots and cross-bar curving as a means for covering one end of the belt to the clamp with its free end lying in rear of the buckle when the clamp is in engagement with the buckle, as set forth.

701,092. LOUGH-LEAF LIDDER. FRANCIS S. SWEENEY, Chicago, Ill., assignor to Erik L. King, Chicago, Ill. Filed Feb. 27, 1902. Serial No. 65,945. (No model.)

Claim.—1. A device of the class described, in which is combined parallel sliding-plates, expansion-plates arranged at right angles thereto, a connecting-plate having obliquely-disposed slots therein extending from near opposite edges toward the middle, said slots upon said opposite expansion-plates, one set connecting with one and the other with the other of said obliquely-disposed slots, and means for moving said connecting-plate longitudinally in opposite direction.

2. The combination in a device of the class described, of parallel sliding-plates, sliding-slots arranged at right angles thereto, expansion-plates attached to said sliding-plates in planes parallel to the plane of said sliding-slots, a connecting-plate having obliquely-disposed slots therein extending from near opposite edges toward the middle, said slots upon said opposite expansion-plates, one set connecting with one and the other with the other of said obliquely-disposed slots, and an adjusting screw connected with said connecting-plate and revolvable in a stationary bearing.

3. The combination in a device of the class described, of parallel sliding-plates, sliding-slots arranged at right angles thereto, expansion-plates attached to said sliding-plates, a connecting-plate having obliquely-disposed slots therein extending from near opposite edges toward the middle, said slots upon said opposite expansion-plates, one set connecting with one and the other with the other of said obliquely-disposed slots, a sliding cross-bar connecting said expansion-plates, means for preventing the same from moving longitudinally thereof, and a screw revolvable in said cross-bar and in operative connection with said connecting-plate.

4. The combination in a device of the class described, of parallel sliding-plates, expansion-plates attached at right angles thereto and arranged in a common plane, a connecting-plate having slots therein arranged obliquely to each other, means for connecting said slots with said expansion-plates, slotted cross-bars loosely connected with said expansion-plates by means of suitable studs, and a screw arranged longitudinally of said expansion-plates, said screw being revolvable in one of said cross-bars and in operative connection with said slotted connecting-plate, and expansion back plates or shields.

5. The combination in a device of the class described, of parallel sliding-plates, expansion-plates attached at right angles thereto and arranged in a common plane, a connecting-plate having slots therein arranged obliquely to each other, means for connecting said slots with said expansion-plates, slotted cross-bars loosely connected with said expansion-plates by means of suitable studs, a screw arranged longitudinally of said expansion-plates, said screw being revolvable in one of said cross-bars and in operative connection with said slotted connecting-plate, and expansion back plates or shields.

701,093. GAME OR PUZZLE. ANDREW J. TUCK, New Rochelle, N. Y. Filed Aug. 6, 1901. Serial No. 71,054. (No model.)

Claim.—A game or other transparent covered box the bottom of which is constructed on a horizontal surface with gutters descending from either side of the box of the plane around the outer end of the box, similar to the plane of a bowling-alley, with the exception that the gutters are so constructed that the lower edge of either of them as it approaches the outer end, comes so near the cone-shaped hollows that the distance

between the edge of the gutter and the edge of the hollows is less than one-half the diameter of the balls, and less than one-half the diameter of the hollows, and in which the inverted-cone-shaped hollows are so arranged that the distance between the edges of any two of them is less than the diameter of the balls, and less than their own diameter; in connection with ten balls intended to be used in the game of bowling as set forth.

701,094. FIRE-ESCAPE. JAMES STRANAHAN and FRED J. STRANAHAN, Cynthiana, Ind. Filed May 2, 1901. Serial No. 62,417. (No model.)

Claim.—1. In a fire-escape, the combination with a reel and means for regulating the movement thereof, of an extender comprising two hinge-connected sections, and two members fastened respectively to the sections and having interlocking parts, for the purpose specified.

2. The combination of two hinge-connected sections, and two sections fastened respectively to said hinge-connected sections, the two sections having interlocking parts to hold the hinge-connected sections rigid when extended.

3. In a fire-escape, the combination of a box having two of its side walls connected together by a hinge and one of said walls being connected by a hinge to the body of the box, a drum and regulating device mounted in the box, a rope carried on the drum and guided over the hinge-connected walls thence when said walls are thrown outward, and trans-sections respectively carried on the hinge-connected sections of the box, said trans-sections having interlocking parts connected together when the hinge-connected walls of the box are thrown into the extended position.

4. The combination of a drum, a rotary shaft carrying it, a dog-carrier fastened to the shaft, a dog mounted on the carrier, a shaft mounted stationary in alignment with the rotary shaft, a clutch member loose on the stationary shaft and isolating the dog-carrier and dog, said dog working with the interior of the clutch member, weighted arm pivoted on the clutch member, and having brake-fingers, a stationary member forming a braking-surface with which the brake-fingers coast, and springs actuating the weighted arm to hold them yieldingly against centrifugal motion.

701,095. PLATE-CHIFT. ELMER S. SUMNER, Milton, Pa. Filed Feb. 22, 1902. Serial No. 63,965. (No model.)

Claim.—1. In a plate-chift, the combination with a carriage bearing a plate, of a rack shaft having arms pivotedly connected to said carriage, levers bearing hooks engaging said rack-shaft, catches for moving said rack-shaft in place, a shift-key and means for connecting said key to said carriage to shift said plate, substantially as described.

2. In a plate-chift, the combination with a carriage, of guide-bar, a cable mounted on said guide-bar, and a V-shaped guide mounted on said

carriage and embracing said guide-bar, one of the arms of said guide being pointed to form an index for said scale, substantially as described.

3. In a platen-shift, the combination with a carriage-frame bearing a platen, four pivoted arms of equal length supporting said carriage-frame, said arms being so inclined that the fall of one side of the carriage is compensated by the rise of the other side so that the axis of the platen is in the same horizontal plane after the shift as it was initially, substantially as described.

701,096. LINE-SPACING MECHANISM FOR TYPE-WRITERS. RALPH S. GUNTER, Milton, Pa. Filed Feb. 3, 1902. Serial No. 68,176. (No model.)

Claim.—1. In a spacing device, the combination with a platen, of a ratchet bearing teeth having concave inclines, a rack-arm, an above-pawl carried by said rack-arm and comprising a tail and a hooked bill, said tail being located to come in contact with said rack-arm to limit the movement of said pawl, and means for actuating said rack-arm, substantially as described.

2. In a spacing device, the combination with a platen bearing a

ratchet having concave teeth, of a bar bearing a rack-arm, an above-pawl having a tail located to come in contact with said arm to limit the movement of said pawl, said pawl having a hooked bill designed to engage said concave teeth to hold said platen against rotation when said tail is in contact with said arm, and means for actuating said rack-arm, substantially as described.

701,097. WINDOW FRAME AND CASE. HENRY G. SMITH, Cambridge, Mass., assignor to Smith-Warren Company, Boston, Mass., a Corporation of Massachusetts. Filed Jan. 2, 1902. Serial No. 68,188. (No model.)

Claim.—1. In a sheet-metal window-cash the alternate rolls and stiles of which form a spiral connection with each other, clips extending from the sides of one and slotted openings in the sides of the other adapted to receive said clips that a spiral connection may be formed between roll and stile substantially as described.

2. A metallic window-cash, each roll of which has extending from its side flange the clips δ^2 , stiles having the slot δ^1 cut therein to receive said clips δ^2 , and a series of clips extending from stile and roll above and adapted to engage the corresponding rolls and stiles so that an interlocking spiral connection may be formed between the same, substantially as described.

3. In a metallic window, a casing having a reinforcing division-plate, a detachable flange-plate adapted to receive the inner edge of said division-plate, means connecting with said casing and providing a runway for the same substantially as described.

4. In a metallic window, a casing having a back plate, two flange-forming side plates, a reinforcing division-plate, and a detachable flange-plate receiving in a head-forming means the inner edge of said division-plate and by its edges turning to make attachment with the side plate above said, providing a gateway for the same substantially as described.

5. A window-cash having a shoe to press against the window-frame, a spring communicating with said shoe that the same may bear with a yielding pressure against said window-frame, a rear stop for the rotation of said spring, held to the window-frame by flexible solder, and means for increasing or diminishing the projection of said shoe from said spring that the tension of the spring upon the shoe may be correspondingly increased or diminished, substantially as described.

6. A window-cash having a shoe to press against the window-frame, a spring communicating with the said shoe that the same may bear with a yielding pressure against the window-frame, a rear stop for the rotation of said spring, held to the cash by flexible solder over an opening therein, and means for varying the tension of said spring upon said shoe consisting of a bolt and nut, the same so acting as a means of communication between the spring and the shoe above said, that as the bolt is turned out or in the distance between the shoe and the spring is increased or diminished which results as the shoe presses against the window-frame in a corresponding increase or diminishing of the tension of the spring upon the shoe, substantially as described.

7. In a window having an overbalanced cash, a means for connecting the cash with the cord or chain supporting the overbalancing-weight, which means consists of a hook within the side cash-roll making a pivotal connection with its inner side then proceeding upward and outward to make a detachable connection with the weight-bearing cord or chain through an opening in the outer side of the cash-roll, substantially as described.

701,098. CHERRY-CUTTER. WILLIAM J. SPILLER, Pullman, Wash., assignor of one-half to John W. Spiller, Pullman, Wash. Filed May 10, 1901. Serial No. 68,189. (No model.)

Claim.—1. In a cherry-cutter, a support, a revolvable table mounted on the support, a segmental scale carried by the support, an arm mounted on the pivot of the table and extending over the scale, a stop adjustably secured on the scale and between which and the end of the scale the arm is adapted to be moved to permit the table to be turned a predetermined distance at each movement of said arm, and a dog pivoted to the center

end of the arm and having a curved face adapted to engage the table to lock the arm thereon, as set forth.

2. In a cherry-cutter, a base provided with stanchions on its upper face, a cross-head mounted on the stanchions above the base and provided at its center with a stanchion projecting from its upper face, and a reciprocating knife having guided movement on the stanchion of the cross-head and one of the stanchions of the base, as set forth.

3. In a cherry-cutter, a base provided with stanchions projecting from its upper face, one of the stanchions being longitudinally grooved, a slotted cross-head adjustably secured on the stanchions and provided at its center with a longitudinally-grooved stanchion on its upper face, a knife mounted in the groove of the said stanchions and the slot of the cross-head, a pivoted lever on the cross-head, and a link connecting the lever with the knife, as set forth.

4. A cherry-cutter, comprising a base, provided with stanchions, a cross-head adjustably supported on the stanchions above the base, and provided with a stanchion at its center, a reciprocating knife having guided movement in one of the stanchions of the base and the stanchion of the cross-head, a revolvable table mounted on the base, a scale carried by the base, an adjustable stop on the scale, and an arm connected with the base and extending over the scale, as set forth.

5. A cherry-cutter, comprising a base provided with stanchions on its upper face, a slotted cross-head adjustably mounted on the stanchions and provided at its center with a stanchion, a reciprocating knife working in the slot of the cross-head and having guided movement in the stanchion of the said cross-head and one of the stanchions of the base, a revolvable table mounted on the base, a scale carried by the base and provided with an adjustable stop, an arm mounted on the pivot of the table and extending over the scale, and means for locking the arm to the table, as set forth.

701,099. SPRING-CLAMP THROUGH-GRABBLE FOR HARVESTERS. JOHN F. STEWART, Chicago, Ill. Filed Nov. 14, 1901. Serial No. 68,178. (No model.)

Claim.—1. In a harvester, the guide-revolving platform, the one platform having the flanged bar δ , means whereby it may be grasped by a latching device, a bar, as δ , also secured to the said platform and having means by which the end of the tongue may be securely connected to δ , the tongue having the attachment at its rear end adapted to engage the said bar δ , and also having upon its middle provided with a spring-latch adapted to support and engage the said bar δ , substantially as described.

2. In a harvesting-machine, a latch adapted to connect one part of said machine to another part of said machine, consisting of the body A , secured to one portion of the machine, and having a nut to receive another portion of said machine to be held thereby and having a latch consisting of the U-shaped bolt B , upon one of the legs of said U-shaped bolt the spring C , and the other leg D of the said U-shaped bolt guided in the said body, thus forming the latch, substantially as described.

701,100. GAS-BURNING-GRUVE. SAMUEL STEWART, Newark, N. J. Filed May 14, 1901. Serial No. 68,180. (No model.)

Claim.—1. In a gas-burner having a series of upright tubular burners, the combination, with the casing having sides, back, top and bottom, and front provided with opening e as set forth, and air-chamber A extended under the bottom, of the horizontal grate d supporting a bed of terracotta fragments as set forth, the series of upright tubular burners having each the cylindrical body g extended through the bottom of the casing, and projected upwardly nearly to the grate, a gas-pipe c extended through each cylindrical body to support the burner and provided with gas-jet as set forth, and each burner having the flame-screen f upon the top and the perforated shell g' upon the bottom extending downwardly into the air-chamber, whereby the gas and air are mixed in the several burners, and a series of flames are applied to the under side of the grate to render its contents incandescent, substantially as herein set forth.

each the cylindrical body g extended through the bottom of the casing and projected upwardly nearly to the grate, and a gas-pipe c extended through each cylindrical body to support the burner, and provided with gas-jet as set forth, and each burner having the flame-screen f upon the top and the perforated shell g' upon the bottom extending downwardly into the air-chamber, whereby the gas and air are mixed in the several burners, and a series of flames are applied to the under side of the grate to render its contents incandescent, substantially as herein set forth.

2. In a gas-burner having a series of upright tubular burners, the combination, with the casing having sides, back, top and bottom, and front provided with opening e as set forth, and air-chamber A extended under the bottom, of the horizontal grate d supporting a bed of terracotta fragments as set forth, the series of upright tubular burners having each the cylindrical body g extended through the bottom of the casing, and projected upwardly nearly to the grate, a gas-pipe c extended through each cylindrical body to support the burner and provided with gas-jet as set forth, and each burner having the flame-screen f upon the top and the perforated shell g' upon the bottom extending downwardly into the air-chamber, and a partition extended upwardly in contact with the grate inside the casing, forming the air-flue f' having connection with the air-box A , and having flange-openings c' into the space above the grate, to supply the apartment with heated air independently with the products of combustion.

3. In a gas-burner having a series of upright tubular burners, the combination, with the casing having sides a , back a' , bottom b , top c , and air-chamber A extended under the bottom, with partition f extended upward from the bottom, forming an air-flue f' to connect the chamber A with the interior of the casing below the top c , a horizontal grate within the casing supported upon the partition and upon the front of the casing, the latter having the opening e as set forth, and the series of tubular burners g having their lower ends projected through the bottom b and provided each with perforated shell g' and their upper ends provided with flame-screens f in proximity to the grate, and each burner having the gas-pipe c extended within the casing and supplied with gas-jet, the whole arranged and operated substantially as herein set forth.

4. A gas-burner comprising the casing closed upon the top and three sides and containing the grate with a bed of terracotta fragments thereon and an opening below the grate for the radiation of heat, partitions within the rear and sides of the casing forming flange-openings into the top of the casing, burners beneath the grate, an air-box and pipe connecting each burner and flue with the external atmosphere, the bed of terracotta being in contact at its edges with the partitions to heat the same and the air within the flue.

5. In a gas-burner, the combination, with a casing containing a grate and a bed of terracotta fragments thereon, and having an opening below the grate for the radiation of heat, of a tubular burner or burners extended from the bottom of the casing upward nearly to the grate with gas-supply in the bottom of each burner, a flame-screen at the top of the burner next the grate, an air-box below the casing with air-supply thereto, and a perforated shell extended from the burner into the air-box to receive the air therefrom.

701,101. BOTTLE-DROPPER. FREDERICK STEIN, Philadelphia, Pa., assignor of one-half to Frederick E. Glander, Philadelphia, Pa. Filed Nov. 15, 1901. Serial No. 68,205. (No model.)

Claim.—1. The combination with the neck of a bottle having a groove therein, of a latching device to said bottle, said latching device having an annular head at its lower extremity adapted to coast with said groove whereby the latching is secured to said bottle, and a laterally-extending flange adapted to project over the mouth of the bottle.

2. The combination with the neck of a bottle, of an annular groove therein, a bushing within said neck, having a head at its lower portion adapted to be seated in said groove, a flange on the upper portion of said bushing adapted to project over the extremity of the bottle, and a stopper adapted to enter said bushing.

3. The combination with the neck of a bottle having a groove therein, of a bushing having a head adapted to coast with said groove, a flange on said bushing extending over the mouth of the bottle, and an independent stopper having an extension entering said bushing and existing in forming a tight joint between said neck and bushing.

701,102. VESSEL FOR CONTAINING LIQUIDS. LOUIS J. TARDY, Vermeil, France, assignor of one-half to Jean Pierre Arsène Elie Henri Cheumont, Vermeil, France. Filed Sept. 28, 1891. Serial No. 75,745. (No model.)

Claim.—1. A controlling device indicating additions to or subtraction of liquid in the containing vessel, said device being essentially constituted by floats provided with arms displaced within internally-grooved transparent tubes.

2. In a controlling device, the combination of two floats provided with arms one of these floats partially entering within the other in such a manner that its arms are caused to approach the center of the tube, one of the floats serving for direct control and the other for indirect or inverse control, the level of the liquid being thus checked whether it moves from below upward or from above downward.

3. In a controlling device arranged within a bottle, the combination of two internally-grooved tubes, one of which is rigidly fixed, extends throughout the entire length of the bottle and is provided with a ring adapted to rotate around it, while the second is expanded from the ring of the first by a universal joint, the height of this second tube, which is provided with a counterweight, being equal to the diameter of the bottle; floats for direct and for indirect or inverse control being provided in each of these tubes respectively.

4. In a control appliance, the combination with a bottle, and the two tubes and floats of means with apertures arranged as baffles for the purpose of preventing fraud.

5. In a controlling appliance, the combination of an internally-grooved tube housing a float for direct control and provided with means for reverse control.

6. In a controlling appliance, the combination with the float for direct control of a means arranged within the glass tube and serving to wedge or lock the float when the bottle is inverted for preventing this float from rising under the influence of the thrust exercised upon it by the liquid.

701,103. SLIDE-RULE. HOWES TRACHER, New York, N. Y., assignor of one-half to Edwin H. Goodfield, Pittsburgh, Pa. Filed Jan. 27, 1892. Serial No. 91,472. (No model.)

Claim.—1. A slide-rule, bearing two sets of duplicate logarithmic scales, one set upon each side of its longitudinal center, one scale of each set being upon the slide and one upon the base, each scale having a length equal to the graduated length of the rule, both scales of one set reading continuously from left to right, and both scales of the other set reading from center to right and thence from left to center, substantially as described.

2. A slide-rule, composed of two fixed and two movable logarithmic scales, each composed of two equal parts arranged one above the other, having a combined length equal to the graduated length of the rule; one scale of said fixed and movable scales being upon one side of the transverse center of the rule, and beginning on the top and ending on the bottom; and the other of said fixed and movable scales being upon the other side of the transverse center of the rule, and beginning on the

bottom and ending on the top, all being direct scales, substantially as described.

3. A slide-rule bearing two sets of duplicate logarithmic scales, one scale of each set being upon the slide and one upon the base, so arranged that the square root of the base of the system of logarithms of each set is opposite the unit of one scale of the other set, substantially as described.

4. A slide-rule bearing two duplicate logarithmic scales relatively fixed, and so arranged that the square root of the base of the system of logarithms in one scale is approximately opposite the unit of the other scale, substantially as described.

701,104. PLANING-MACHINE. JOHN R. THOMAS, Cincinnati, Ohio, assignor to J. A. Fay & Egan Company, Cincinnati, Ohio, a Corporation of West Virginia. Filed Mar. 5, 1892. Serial No. 7,995. (No model.)

Claim.—1. In a planing-machine, the combination with a lower cutter-head, of a lower chip-breaker therefor and a lower feeding-in roll arranged to be depressed below their normal height by the stock, with means for permitting the chip-breaker to be adjusted with and independently of the lower cutter-head, an upper cutter-head, and upper feeding-in roll and contact means for the stock comprising upper feeding-in roll and a pressure device above the lower cutter-head caused against upward yield.

2. In a planing-machine, the combination with the frame, of a lower cutter-head and an upper feeding-in roll normally positioned uprightly

in height, and a lower feeding-in roll arranged to be held against the stock under yielding pressure, with an adjustable saddle for supporting the lower cutter-head and a chip-breaker therefor, with the chip-breaker adjustable with and independently of the saddle, and arranged to be held against the stock under yielding pressure.

3. In a planing-machine, the combination with the frame, of a lower cutter-head and an upper feeding-in roll normally held against yield in height, a lower feeding-in roll arranged to be held against the stock with yielding pressure, an adjustable saddle for the lower cutter-head, with the lower cutter-head and a chip-breaker therefor supported by the saddle, and the chip-breaker adjustable with and independently of the saddle and arranged to be held against the stock with yielding pressure, and a fast for the chip-breaker adjustable to and from the cutter-head.

4. In a planing-machine, the combination with the frame, of a lower cutter-head and an upper feeding-in roll normally held against yielding movement, and a lower feeding-in roll arranged to yield through pressure of the stock, with an adjustable saddle, a yoke thereon on which the lower cutter-head is mounted, a lower chip-breaker supported by the saddle, with the yoke slidable on the saddle transversely of the frame and the chip-breaker adjustable with and independently of the saddle and arranged to yield to pressure of the stock.

5. In a planing-machine, the combination with the frame, of a lower yielding feeding-roll, a lower cutter-head, with a chip-breaker therefor, an arm for the chip-breaker and an arm for the lower yielding feeding-roll having their ends in the same plane, with pressure devices for independently yieldingly raising the lower feeding-roll and the chip-breaker for the lower cutter-head.

6. In a planing-machine, the combination with the frame, of a lower cutter-head, a lower yielding feed-roll, a chip-breaker for the lower cutter-head, with a pressure-lever for the lower yielding feed-roll and a pressure-lever for the chip-breaker, and a rod or shaft about which said levers are fulcrumed for independently yieldingly holding the lower yielding roll and the chip-breaker against the stock.

7. In a planing-machine, the combination of a frame, a lower cutter-head, a roll-bearing extending transversely of the frame, an upper feeding-in roll with bearings rigid with relation to the housing, and long ways connecting the housing and the frame at each side of the frame and extending substantially the entire height of the frame, with a lower feeding-in roll arranged to be depressed bodily by the stock taking through the machine to substantial extent below the line of cut of the lower cutter-head, substantially as described.

8. In a planing-machine, the combination of a frame, a lower cutter-head, a roll-bearing extending transversely of the frame, an upper feeding-in roll with bearings rigid with relation to the housing, and long ways connecting the housing and the frame at each side of the frame and extending substantially the entire height of the frame, with a lower feeding-in roll and a chip-breaker for the lower cutter-head arranged to be depressed bodily by the stock taking through the machine to substantial extent below the line of cut of the lower cutter-head, substantially as described.

9. In a planing-machine, the combination of a frame, a lower cutter-head with axis rigid with relation to the frame, an upper feeding-in roll with axis rigid with relation to the frame, and a lower feeding-in roll arranged to yield to substantial extent below the horizontal plane of the cut of the lower cutter-head, with an adjustable saddle for supporting the lower cutter-head, and a chip-breaker therefor, with the chip-breaker adjustable with the same and arranged to yield to substantial extent below the horizontal plane of the cut of the lower cutter-head independently of the latter, substantially as described.

10. In a planing-machine, the combination of a frame, a lower cutter-head with axis rigid with relation to the frame, an upper feeding-in roll with axis rigid with relation to the frame, and a lower feeding-in roll arranged to yield to substantial extent below the horizontal plane of the cut of the lower cutter-head, with an adjustable saddle for the lower cutter-head, with the lower cutter-head and a chip-breaker therefor supported by the saddle, with the chip-breaker adjustable with and independently of the saddle and arranged to yield to substantial extent below the horizontal plane of the cut of the lower cutter-head independently of the latter, with a separable fast for the chip-breaker adjustable to and from the cutter-head, substantially as described.

11. In a planing-machine, the combination of a frame, a lower cutter-head with axis rigid with relation to the frame, an upper feeding-in roll with axis rigid with relation to the frame, and a lower feeding-in roll arranged to yield to substantial extent below the horizontal plane of the cut of the lower cutter-head, with an adjustable saddle for the lower cutter-head, with the lower cutter-head and a chip-breaker therefor supported by the saddle, with the chip-breaker adjustable with and independently of the saddle and arranged to yield to substantial extent below the horizontal plane of the cut of the lower cutter-head independently of the latter, with a fast for the chip-breaker movable with relation thereto, with

means for adjusting the fast to and from the vertical plane of the cutter-head, substantially as described.

12. In a planing-machine, the combination of a frame, a lower cutter-head with axis rigid with relation to the frame, an upper feeding-in roll with axis rigid with relation to the frame, and a lower feeding-in roll arranged to yield to substantial extent below the horizontal plane of the cut of the lower cutter-head, with an adjustable saddle for the lower cutter-head, with the lower cutter-head and a chip-breaker therefor supported by the saddle, with the chip-breaker adjustable with and independently of the saddle and arranged to yield to substantial extent below the horizontal plane of the cut of the lower cutter-head independently of the latter, with a fast for the chip-breaker movable with relation thereto, with means for adjusting the fast to and from the vertical plane of the cutter-head, and means for adjusting the limit of upward movement of the chip-breaker, substantially as described.

13. In a planing-machine, the combination of a frame, a lower cutter-head with axis rigid with relation to the frame, an upper feeding-in roll with axis rigid with relation to the frame, and a lower feeding-in roll arranged to yield below the horizontal plane of the cut of the lower cutter-head, with a saddle in the frame, a yoke slidably mounted on the saddle, with the lower cutter-head journaled in the yoke, a pressure-fast for the cutter-head mounted in the yoke, means for adjusting the saddle with its yoke, cutter-head and pressure-bar simultaneously, an opening in the side of the frame, with a shaft for forcing the yoke with its cutter-head and pressure-fast sidewise for exposing the cutter-head at the side of the frame, substantially as described.

14. In a planing-machine, the combination of a frame, a saddle 68 thereon, means for adjusting the saddle upon the frame, a yoke 74 slidably on the saddle and supporting a cutter-head journaled therein and a pressure-fast thereon, a shaft 75 sliding with the yoke, a worm-wheel 76 caused against sidewise movement in the saddle and having the shaft take therethrough for turning the same, with a worm-rack 77 on the yoke, constructed and arranged for forcing the yoke with its cutter-head and pressure-fast sidewise of the saddle for exposing the cutter-head at the side of the machine, substantially as described.

15. In a planing-machine, the combination of a frame, a lower cutter-head with axis rigid with relation to the frame, an upper feeding-in roll with axis rigid with relation to the frame, and a lower feeding-in roll arranged to yield below the horizontal plane of the cut of the lower cutter-head, with an adjustable saddle for the lower cutter-head with a yoke for the cutter-head sliding longitudinally with relation to the saddle, and the lower cutter-head mounted in the yoke, ways in the yoke, with pressure-bar for the lower cutter-head adjustable in the ways, with means for permitting the sidewise movement of the yoke sidewise for exposing the cutter-head in the side of the frame, substantially as described.

16. In a planing-machine, the combination of a frame, a lower cutter-head with axis rigid with relation to the frame, an upper feeding-in roll with axis rigid with relation to the frame, and a lower feeding-in roll arranged to yield below the horizontal plane of the cut of the lower cutter-head, with an adjustable saddle for the lower cutter-head, with a yoke for the cutter-head sliding longitudinally with relation to the saddle, and the lower cutter-head mounted in the yoke, with a pressure-bar after the cut of the lower cutter-head mounted in the yoke, a fast for the bar, with means for adjusting the fast to and from the vertical plane of the cutter-head, with means for permitting sidewise movement of the yoke for exposing the cutter-head at the side of the machine, substantially as described.

17. In a planing-machine, the combination of a frame, a lower cutter-head with axis rigid with relation to the frame, and a lower feeding-in roll with axis rigid with relation to the frame, and a lower feeding-in roll arranged to yield below the horizontal plane of the cut of the lower cutter-head, with an adjustable saddle, a yoke thereon for the lower cutter-head, and a chip-breaker for the lower cutter-head before the cut and a pressure-bar for the lower cutter-head after the cut mounted on the saddle and adjustable therewith, with means for permitting the sidewise movement of the yoke for exposing the cutter-head at the side of the machine, substantially as described.

18. In a planing-machine, the combination of a frame, a lower cutter-head with axis rigid with relation to the frame, an upper feeding-in roll with axis rigid with relation to the frame, and a lower feeding-in roll arranged to yield below the horizontal plane of the cut of the lower cutter-head, with an adjustable saddle, a yoke thereon for the lower cutter-head, and a chip-breaker for the lower cutter-head before the cut and a pressure-bar for the lower cutter-head after the cut mounted on the saddle and adjustable therewith and movable independently thereof, with means for permitting the sidewise movement of the yoke for exposing the cutter-head at the side of the machine, substantially as described.

19. In a planing-machine, the combination of a frame, a lower cutter-head with axis rigid with relation to the frame, an upper feeding-in roll with axis rigid with relation to the frame, and a lower feeding-in roll

arranged to yield below the horizontal plane of the cut of the lower outer-head, with an adjustable saddle, a yoke thereon for the lower outer-head, and a chip-breaker for the lower outer-head before the cut and a pressure-bar for the lower outer-head after the cut mounted on the saddle and adjustable therewith, with a separate toe for the chip-breaker and a separate toe for the pressure-bar, with means for adjusting the toes to and from each other, with means for permitting sidewise movement of the yoke for exposing the outer-head at the side of the machine, substantially as described.

30. In a planing-machine, the combination of a frame, a lower outer-head with axis rigid with relation to the frame, an upper feeding-in roll with axis rigid with relation to the frame, and a lower feeding-in roll arranged to yield below the horizontal plane of the cut of the lower outer-head, with an adjustable saddle for the lower outer-head and a chip-breaker for the lower outer-head before the cut and a pressure-bar for the lower outer-head after the cut mounted on the saddle and adjustable therewith, with a shiftable yoke interposed between the saddle and the lower outer-head and pressure-bar and means for permitting sidewise movement of the yoke with its outer-head and bar for exposing the outer-head at the side of the machine, with a separate toe for the chip-breaker and a separate toe for the pressure-bar, with means for adjusting the toes to and from each other, with the chip-breaker arranged to yield on the saddle below the horizontal plane of the outer-head, substantially as described.

31. In a planing-machine, the combination of a frame, a lower outer-head with axis rigid with relation to the frame, an upper feeding-in roll with axis rigid with relation to the frame, and a lower feeding-in roll arranged to yield below the horizontal plane of the cut of the lower outer-head, with an adjustable saddle for the lower outer-head, and a chip-breaker for the lower outer-head before the cut and a pressure-bar for the lower outer-head after the cut mounted on the saddle and adjustable therewith, with a yoke interposed between the outer-head with its pressure-bar and the saddle and having shiftable connection with the saddle, with means for permitting sidewise movement of the yoke for exposing the outer-head at the side of the machine, substantially as described.

32. In a planing-machine, the combination of a frame, a lower outer-head with axis rigid with relation to the frame, an upper feeding-in roll with axis rigid with relation to the frame, and a lower feeding-in roll arranged to yield below the horizontal plane of the cut of the lower outer-head, with an adjustable saddle for the lower outer-head, and a chip-breaker for the lower outer-head before the cut and a pressure-bar for the lower outer-head after the cut mounted on the saddle and adjustable therewith, with a yoke interposed between the outer-head with its pressure-bar and the saddle and having shiftable connection with the saddle, with a worm-shaft and worm-gear for sliding the yoke with its outer-head and pressure-bar longitudinally with relation to the saddle for exposing the outer-head at the side of the machine, substantially as described.

33. In a planing-machine, the combination of a frame, a lower outer-head, a roll-bearing extending transversely of the frame, an upper feeding-in roll with bearings rigid with relation to the housing, a lower outer-head saddle, with a feeding-in chip-breaker for the lower outer-head mounted on the saddle, with a lower feeding-in roll, with the lower feeding-in roll and the chip-breaker arranged to be depressed bodily by the stock taking through the machine below the line of cut of the lower outer-head, with a longitudinally-slidable yoke in which the lower outer-head is mounted supported and sliding with relation to the saddle, with a work-support after the lower outer-head, and means for raising and lowering the saddle with its chip-breaker and outer-head to and from the plane of the work-support, with an adjustable pressure device above the lower outer-head, with means for permitting sidewise movement of the yoke for exposing the outer-head at the side of the machine, substantially as described.

34. In a planing-machine, the combination of a frame, a lower outer-head, a roll-bearing extending transversely of the frame, an upper feeding-in roll with bearings rigid with relation to the housing, a lower outer-head saddle, with a feeding-in chip-breaker for the lower outer-head mounted on the saddle, with a lower feeding-in roll, with the lower feeding-in roll and the chip-breaker arranged to be depressed bodily by the stock taking through the machine below the line of cut of the lower outer-head, with a longitudinally-slidable yoke in which the lower outer-head is mounted supported and sliding with relation to the saddle, with a work-support, with means for raising and lowering the saddle with its chip-breaker and outer-head to and from the plane of the work-support, with means for permitting the movement of the chip-breaker and the pressure-bar to and from the plane of the cut of the outer-head, with an adjustable pressure device above the lower outer-head, with means for permitting sidewise movement of the yoke for exposing the outer-head at the side of the machine, substantially as described.

35. In a planing-machine, the combination of a frame, with a lower yielding feed-roll, a rest-shaft, a lower outer-head, with a chip-breaker in advance of the same, with an arm for the chip-breaker and an arm for the lower yielding feed-roll swingingly arranged about the same axis, with pressure devices for independently yieldingly raising the lower feed-roll and the chip-breaker for the lower outer-head, substantially as described.

36. In a planing-machine, the combination of a frame, with a lower yielding feed-roll, a rest-shaft, and an arm extending from the rest-shaft for yieldingly raising the lower roll, a lower outer-head, with a chip-breaker in advance of the same, and a pressure-arm for the chip-breaker cleaved about the rest-shaft, constructed and arranged for swinging the pressure device for the lower yielding roll and the pressure device for the chip-breaker independently about the same shaft, substantially as described.

37. In a planing-machine, the combination of a cutter-head, with a chip-breaker for the outer-head, a plurality of links, with pivots thereon, and connections between the links and the chip-breaker, constructed and arranged for guiding the latter substantially concentrically about the outer-head with its axis maintained substantially in the same plane horizontally with relation to the stock, with means for adjusting the chip-breaker to and from the outer-head, substantially as described.

38. In a planing-machine, the combination of a cutter-head, with a chip-breaker for the outer-head, a plurality of links, with pivots thereon, and connections between the links and the chip-breaker, constructed and arranged for guiding the latter substantially concentrically about the outer-head with its axis maintained substantially in the same plane horizontally with relation to the stock, with a spring for yieldingly holding the chip-breaker against the stock, substantially as described.

39. In a planing-machine, the combination of a cutter-head, with a chip-breaker for the outer-head, a plurality of links, with pivots thereon, and connections between the links and the chip-breaker, constructed and arranged for guiding the latter substantially concentrically about the outer-head with its axis maintained substantially in the same plane horizontally with relation to the stock, with a spring for yieldingly holding the chip-breaker against the stock, with an adjustment for the spring, substantially as described.

40. In a planing-machine, the combination of a cutter-head upright, a cutter-head housing thereby, with means for raising and lowering the outer-head housing with relation to the upright, bearings in the housing for the outer-head, with an extension toward each side of the outer-head in the housing, a secondary housing for the extension, with a plurality of links pivoted in the secondary housing, a chip-breaker, and a pivotal connection between each of the links and the chip-breaker, constructed and arranged for causing the chip-breaker to be moved with its parts maintained substantially in the same relative horizontal plane, with means for adjusting the bearings on the extensions to and from the outer-head, substantially as described.

41. In a planing-machine, the combination of a cutter-head upright, a cutter-head housing thereby, with means for raising and lowering the outer-head housing with relation to the upright, bearings in the housing for the outer-head, with an extension toward each side of the outer-head on the housing, a secondary housing for the extension, with a plurality of links pivoted in the secondary housing, a chip-breaker, and a pivotal connection between each of the links and the chip-breaker, constructed and arranged for causing the chip-breaker to be moved with its parts maintained substantially in the same relative horizontal plane, and an adjustable stop for limiting the movement of the chip-breaker, substantially as described.

42. In a planing-machine, the combination of a cutter-head upright, a cutter-head housing adjustable with relation thereto, bearings for the housing, a cross-girth connecting the bearings, and a pressure-foot extending above the bed between the vertical spindles connecting with the cross-girth, with a pressure-bar for the upper outer-head between the cross-girth and outer-head bearings, with means for adjusting the pressure-bar independent of the pressure-foot, substantially as described.

43. In a planing-machine, the combination of a cutter-head upright, a cutter-head housing thereby, with means for raising and lowering the outer-head housing, vertical side spindles, a cross-girth for the housing, with a pressure-bar for the outer-head between the vertical plane of the cross-girth and the outer-head, with means for adjusting the pressure-bar, and a pressure-foot, with a bracket, extending above the bed of the machine between the longitudinal planes of the vertical spindles, with an adjustment between the bar and bracket, and arranged to steady the pressure-foot from the cross-girth, substantially as described.

44. In a planing-machine, the combination of a cutter-head upright, a cutter-head housing thereby, with means for raising and lowering the outer-head housing, vertical side spindles, a cross-girth for the housing, with a pressure-bar for the outer-head between the vertical plane of the girth and the outer-head, with means for adjusting the pressure-bar, and a pressure-foot, with a bracket, extending above the bed of the machine

between the longitudinal planes of the vertical spindles, with an adjustment between the bar and bracket, means for adjusting the pressure-foot and the bracket, and arranged to steady the pressure-foot from the girth, substantially as described.

45. In a planing-machine, the combination with a lower outer-head, of a lower chip-breaker thereon and a lower feeding-in roll arranged to be depressed below their normal height by the stock, with means for permitting the chip-breaker to be adjusted with and independently of the lower outer-head, and upper feeding and contact flange for the stock comprising upper feeding-in roll and a pressure device above the lower outer-head secured against upward yield.

46. The combination, in a planing-machine having upper and lower outer-heads, of the frame which carries the top feeding-roll and which extends transversely of the main frame, with long ways extending substantially the entire height of the frame inside the main frame, means for adjusting said frame and thereby giving disableness adjustment to the top feeding-roll at both ends with means for driving the top feeding-roll.

47. The combination, in a planing-machine with a main frame having upper and lower outer-heads mounted thereon, a roll-bearing extending transversely of the main frame, an upper feeding-in roll therein, and long ways connecting the bearing and the main frame at each side of the main frame inside the main frame and extending substantially the entire height of the main frame, with a lower feeding-in roll, with means for driving said upper feeding-in roll from the main frame.

48. In a planing-machine, the combination of a frame having upper and lower outer-heads mounted thereon, and a roll-bearing, which carries the top feeding-roll adjustable as an entirety while carrying said rolls and thereby giving disableness adjustment to said top feeding-roll at both ends, means for performing said adjustment, with said roll-bearing extending transversely of the frame, and long ways connecting the bearing and frame at each side of and inside the frame and extending substantially the entire height of the frame, a lower feeding-in roll, operating on the frame, operating on the said feeding-in roll in the bearing, and over expansion-gearing at the feeding-in side of said feeding-in roll between the gearing in the frame and the gearing on the feeding-in roll, substantially as described.

49. In a planing-machine, the combination of a frame having upper and lower outer-heads mounted thereon, and a roll-bearing, which carries the top feeding-roll, adjustable as an entirety while carrying said rolls and thereby giving disableness adjustment to said top feeding-roll at both ends, means for performing said adjustment, with said roll-bearing extending transversely of the frame, and long ways in the inside of the frame at each side of the frame connecting the bearing and the frame and extending substantially the entire height of the frame, a lower feeding-in roll, with means for driving the top feeding-roll from the main frame, substantially as described.

50. In a planing-machine, the combination of a frame having upper and lower outer-heads mounted thereon, and a roll-bearing, which carries the top feeding-roll, adjustable as an entirety while carrying said rolls and thereby giving disableness adjustment to said top feeding-roll at both ends, means for performing said adjustment, with said roll-bearing extending transversely of the frame, and long ways in the inside of the frame at each side of the frame connecting the bearing and the frame and extending substantially the entire height of the frame, a lower feeding-in roll, with means for driving the top feeding-roll from the main frame, substantially as described.

701,105. FLANK FOR SAND HOLDER. ROBERT C. TOLME, Wilmington, Del., assignor to Lobell Car-Wheel Company, Wilmington, Del., a Corporation of Delaware. Filed June 28, 1901. Serial No. 68,126. (No model.)

Claim.—1. The combination in a flask of a fixed section, a movable section mounted within the fixed section, ribs or partitions carried by the movable section, said section being open at the top so that the sand can be packed into the mold prior to compression of the same with a single device constructed to perform the double function of holding the movable section in either its elevated or its depressed position, substantially as described.

2. The combination of a flask made in two parts, one part being fixed and the other part being movable, vertical slots in one part, and legs

on the other part entering said slots, and stops to limit the movement of the movable part of the flask, substantially as described.

3. The combination of a two-part flask, one part being fixed, the other part being movable within the said fixed part and having stops to limit the movement of the said movable part, latches on one part and lugs on the other part, said latches and lugs being so arranged that the latches will support the movable part when raised and hold it down in position when depressed, substantially as described.

4. The combination of a pattern A, a shell-ring B mounted on the pattern, a two-part flask D, one part E being fixed, bolts securing the said fixed part to the shell-ring, the movable part F arranged to slide within the fixed part, said movable part having an annular rib or partition, and radial ribs extending from the annular rib to the outer portion of the section, a stop to limit the upward movement of the movable section, and means for holding the movable section either in its raised or depressed position, substantially as described.

701,106. KITE. ROBERT J. TRAMER, Jersey City, N. J. Filed Feb. 14, 1902. Serial No. 94,090. (No model.)

Claim.—1. The combination of a kite, an acoustical instrument attached thereto, a cord attached to the kite, and a telephone receiver connected to the cord.

2. A kite having a whistle attached thereto, and an air-tube of uniform interior diameter located at one side of the whistle to receive the currents of air and to deliver them to the whistle, said air-tube having therein at its receiving end an inwardly-projecting funnel-shaped and piece.

3. The combination of a kite, an acoustical instrument attached thereto, a cord connected to the kite, and a telephone receiver attached to the cord, said receiver comprising a tube with a diaphragm therein, and an interior rod adapted to have the cord connected to it.

701,107. PERFORATING-MACHINE. WILLIAM E. TRIM, Lynn, Mass. Filed Oct. 14, 1901. Serial No. 73,692. (No model.)

Claim.—1. A perforating-machine comprising a work-supporting bed, a punch movable longitudinally toward and from the bed and laterally over it, mechanism for reciprocating the punch both longitudinally and laterally to give the punch work-penetrating movements and stop-by-stop work-feeding movements, a flexible bed-feeding strip and means for guiding said strip between the bed and the punch, said strip feeding the cutting face of the bed, the work-penetrating movement of the punch causing it to engage said feeding-strip so that the work-feeding movements of the punch also feed the feeding-strip step by step.

2. A perforating-machine comprising a work-supporting bed, a punch reciprocated longitudinally toward and from the bed and laterally over it, a flexible bed-feeding strip guided between the bed and punch, the punch in its cutting movement passing through the work and strip simultaneously, and means for relieving the strip from binding-pressure during the feeding movement.

3. A perforating-machine comprising a work-supporting bed, a punch movable longitudinally toward and from the bed and laterally over it, a flexible bed-facing strip, means for guiding said strip between the punch and bed, means for reciprocating the punch longitudinally, said means having provision for forcing the punch through the work into the strip, and then slightly rotating the punch to relieve its pressure on the strip without disengaging it from the strip, and means for reciprocating the punch laterally, said means being organized to give the punch its work-feeding movement while it is in said slightly-rotated position, whereby the strip although relieved from binding-pressure is positively engaged and fed by the punch.

4. A perforating-machine comprising a work-supporting bed, a punch movable longitudinally toward and from the bed and laterally over it, mechanism for reciprocating the punch both longitudinally and laterally to give the punch work-penetrating movements and step-by-step work-feeding movements, a reel mounted on the frame of the machine, a rolled flexible bed-facing strip mounted thereon, and means for guiding said strip from the reel between the bed and punch.

5. A perforating-machine comprising a work-supporting bed having a strip-guide at one end, a punch movable longitudinally toward and from the bed and laterally over it, mechanism for reciprocating the punch both longitudinally and laterally to give the punch the described work-penetrating and feeding movements, and an elongated flexible bed-facing strip engaged with said guide, the latter being arranged to direct said strip between the bed and punch.

6. A perforating-machine comprising a work-supporting bed having a strip-guide at one end, a punch movable longitudinally toward and from the bed and laterally over it, mechanism for reciprocating the punch both longitudinally and laterally to give the punch the described work-penetrating and feeding movements, an elongated flexible bed-facing strip engaged with said guide, the latter being arranged to direct said strip between the bed and punch, and means adjacent to said guide for supporting the reserve portion of said strip.

7. A perforating-machine comprising a horizontal work-supporting bed, a vertical punch-bar having a perforating-punch located over said bed, a slide movable horizontally over the bed and having guides in which the punch-bar is movable vertically, a flexible bed-facing strip, means for guiding said strip between the bed and the punch, means for reciprocating the punch vertically, said means having provision for forcing the punch into the facing-strip and leaving it temporarily in engagement with the said strip, and means for reciprocating the slide horizontally to give the punch its work-feeding and return movements, the last-mentioned means having provision for giving the punch its work-feeding movement while it is engaged with the facing-strip, whereby the strip is fed positively step by step with the work.

8. A perforating-machine comprising a horizontal work-supporting bed, a vertical punch-bar having a perforating-punch located over said bed, a slide movable horizontally over the bed and having guides in which the punch-bar is movable vertically, a flexible bed-facing strip, means for guiding said strip between the bed and the punch, means for reciprocating the punch vertically, said means having provision for forcing the punch into the facing-strip and leaving it temporarily in engagement with

the said strip, means for reciprocating the slide horizontally to give the punch its work-feeding and return movements, the strip being fed by the punch with the work, and means for varying the length of the horizontal movements of the punch to vary the feed of the work and strip.

701,108. WRENCH. WILLIAM H. THOMAS, JR., New York, N. Y. Filed Sept. 26, 1901. Serial No. 74,573. (No model.)

Claim.—1. A wrench, comprising a fixed jaw having gripping-surfaces on its opposing edges and provided with a slot having a plurality of bearings, and a movable hook-jaw having a pivot working in the slot of the fixed jaw and adapted to be inserted in said bearings, as set forth.

2. A wrench comprising a handled jaw having segmental gripping-surfaces and provided with a plurality of connected angular slots, and a hook-jaw having a pivot for engaging the said slots to change the fulcrum of the hook-jaw on the handled jaw to permit it to work in combination with either gripping-surface of the handled jaw, as set forth.

3. A wrench comprising a handled jaw having gripping-surfaces standing at angles one to the other, the said jaw also having angular slots arranged one above the other and a slot connecting the angular slots, and a hook-jaw having a pivot for engaging the said slots, to allow of changing the hook-jaw relative to the said gripping-surfaces of the handled jaw, as set forth.

4. A wrench comprising a handled jaw having spaced side slots terminating in angular ends and a connecting-slot for connecting the said side slots with each other, and a hook-jaw having a pivot for engaging the said slots, as set forth.

5. A wrench, comprising a handled jaw having gripping-surfaces on its opposing edges and provided with an angular slot, the ends of which are opened to form bearings, and a hook-jaw, forced to straddle the handle-jaw and provided with a pivot connecting the members of the fork and working in the slot of the handled jaw, as set forth.

701,109. PAPER-FOLDING APPARATUS. THOMAS L. VALENTINE, Fort Atkinson, Wis., assignor to the Greenway Package Manufacturing Company, Chicago, Ill., a Corporation of Illinois. Filed Dec. 26, 1902. Serial No. 41,471. (No model.)

Claim.—1. The combination with a rotary casing, of plates 4, 4' secured to the ends thereof, each of the said plates having integrally formed tubular portions 6 and 6' whereby the portion 6 extends into the interior of the casing and is adapted to communicate therewith, and the portion 6' projects outwardly and is adapted to serve as a journal.

2. The combination of a rotary structure comprising inner and outer slightly-curved rotary casings, journal members secured to the opposite

ends of the outer casing, each of said members being constructed with inwardly and outwardly projecting tubular portions having a common base whereby the outwardly-projecting portion is adapted to serve as a journal and the inwardly-projecting portion extends into the interior of the outer casing and is adapted to communicate therewith, and is also adapted to engage the inner casing, pipes extending through the bases of said journal members and into the inner casing, pipes fitted to the outer ends of the journal portions, and stuffing-boxes at the joints of the said pipes and journal portions and also at the points of entry into the interior casing of the pipes arranged in the bases of said journal members, substantially as described.

3. The combination with the inner and outer rotary casings, of a tubular structure secured to one of the ends of the outer casing and extended inwardly to the inner casing, a pipe or tube arranged within said tubular structure and extended into the inner casing, and a stuffing-box at the junction of the tubular structure and the end of the inner casing, the said stuffing-box including the tube or pipe within the tubular structure.

4. The combination with a rotary casing, of tubular structures providing passage-ways to the opposite ends of the casing, a distribution-pipe disposed below the casing, connecting-pipes connecting the said distribution-pipe with the tubular structures which communicate with the interior of the casing, a steam-jet at the junction of the distributing-pipe and one of said connecting-pipes, and a check-valve in said connecting-pipe above the steam-jet, the said check-valve being adapted to permit the flow of fluid in an upwardly direction but to prevent its flow in a downwardly direction, substantially as set forth.

5. The combination with the inner and outer rotary casings, of a tubular structure providing an opening through the outer casing and adapted to afford means of communication with the interior of said casing, an inlet-pipe connected with said tubular structure for supplying the same with fluid for the interior of the outer casing, a small pipe or tube arranged within said inlet-pipe and said tubular structure and extended through the end of the inner casing so as to communicate with the interior of said casing, the said small pipe or tube being extended out of the inlet or supply pipe and the pipe connected with said small pipe or tube, whereby the latter can be supplied with fluid for the interior casing, substantially as set forth.

6. The combination with the casing providing a chamber for the temperature-varying fluid, of a supply-pipe extending from the casing to a source for supplying a fluid under ordinary temperature, and provided with a steam-jet, whereby the contents of the receptacle can be first heated by filling the casing with such fluid, and then heating the same, and can then be cooled by shutting off the jet and admitting more of such fluid, an outlet by which the casing can be drained, and a second supply-pipe leading from a source for supplying a cooling fluid at a relatively cooler

temperature, whereby the contents of the receptacle can be further cooled by admitting such relatively cooler fluid to the casing after the casing has been emptied.

7. The combination with a casing providing a fluid-chamber of means for supplying said chamber with a heating fluid, a plurality of sources for supplying a plurality of cooling fluids of different temperatures, and means for conveying each of said fluids to the casing.

8. The combination with the casing providing a chamber for the temperature-varying fluid, of sources for supplying a plurality of cooling fluids, each at different temperature, pipes connecting both of said sources with the casing, and a steam-jet for heating the fluid in the casing.

9. The combination of the casing providing a chamber for the temperature-varying fluid, a source for supplying water at ordinary temperature, and another source for supplying brine at a lower temperature, pipes connecting both of said sources of supply with the casing, and a steam-jet or like device for heating the water supplied under ordinary temperature.

10. The combination with the casing providing a chamber for the temperature-varying fluid, of a source for supplying water under ordinary temperature, and another source for supplying brine at a lower temperature, pipes connecting both of said sources with the casing, a steam-jet for heating the water supplied to such casing, an outlet by which the water can be drained from the casing, and a return-pipe connecting the casing with the source for supplying brine, whereby the brine can be returned from the casing to its source of supply.

11. The combination with the casing providing a chamber for the temperature-varying fluid, of a plurality of sources for supplying the casing with a plurality of cooling fluids of different temperatures, and a device for heating one of such fluids when desired, whereby such fluid can be caused to serve as either a heating or a cooling fluid at will.

12. The combination with the casing providing a chamber for the temperature-varying fluid, of means for supplying fluid at ordinary temperature, means for supplying fluid at a relatively lower temperature, means for conveying each of said fluids to the casing, and a device for heating the fluid supplied at ordinary temperature when desired, whereby such fluid can be employed as either the heating or the cooling fluid at will, and also whereby its cooling action can be supplemented by the cooling action of the fluid supplied at a lower temperature.

13. The combination with the casing providing a chamber for the temperature-varying fluid, of sources of supply C and D for fluids at different temperatures, pipes 36 and 39 extending respectively from said sources C and D, a pipe 37 arranged as an inlet-pipe for the casing, a steam-pipe 40, a pipe 41 connecting the pipe 40 with the inlet-pipe 37, the said pipe 41 having a steam-jet 42, a distribution-pipe 44, a pipe 45 extending upwardly from the pipe 44 and having a connection with the other end of the casing, an overflow-pipe 43 connected with the pipe 45, and a return-pipe 46 connecting the pipe 45 with the source of supply D, substantially as described.

701,110. RAY-RACK. HOWE P. VERNER, Waterville, Kans., assignor of two-thirds to August Wippl and William Wendell, Kansas. Filed Apr. 12, 1902. Serial No. 148,086. (No model.)

Claim.—1. A ray-rack consisting of a front cross-bar, a rear cross-bar and intermediate cross-bars, longitudinal beams resting upon the rear and intermediate cross-bars at each side of their centers, being secured to said cross-bars, the forward ends of which beams abut against the rear flange of the forward cross-bar, clamps securing the said beams to the forward cross-bar, body-boards located at the outer sides of the said beams, resting upon and secured to the upper flange of the intermediate and rear cross-bars, the forward ends of which body-boards extend into the recesses in the forward cross-bar and are secured to the same, and central body-boards located between the beams, which central body-boards rest upon the rear and intermediate cross-bars and abut against the rear surface of the forward cross-bar, as described.

2. In a ray-rack, the combination with a body-section comprising a front cross-bar, secured at its ends to each side of its center, intermediate and rear cross-bars parallel with the forward cross-bar, longitudinal beams resting upon the intermediate and rear cross-bars, being

mination with an angle-shaped slot having the ends *ab*, then making two points of the same dimension, one of which points extends out from the body of the slot at a right angle with the same, and the other of which points extends downward at a right angle from the body of the slot and toward the angle between the two sides of the same, the said two points being for the purpose of connecting the slot to the sides of a cross-frame or upstand.

701,111. EYEGLASSES OR SPECTACLES. WILLIAM L. WALL and LAWRENCE FROST, Philadelphia, Pa., assignors to Wall and Ochs, Philadelphia, Pa., a Firm. Filed July 28, 1901. Serial No. 89,610. (No model.)

2. In a flustering for an ocular or apertic lens, a stud provided with straps having openings therein, and a two-part screw, the members of which are fitted to each other telescopically, the external member passing freely through both straps and said lens, the head of one member of said screw bearing against the adjacent strap and the head of the other member thereof bearing against the end of the first-named member and the surrounding portion of the adjacent strap.

4. In an eyeglass or spectacle fastening, a stud provided with a screw for securing a bridge and nosepiece, and means on said stud for covering the head of said screw, said means consisting of a movable plate which is mounted on said stud independently of said screw.

6. In an *oxyrhina* or *apostrophe*, a stud provided with a screw for securing a bridge and suspension, and means on said stud for covering the head of said screw, said means consisting of a plate which is movably fitted to said stud, and a locking device for said plate, said device consisting of a lip which is connected with said plate and adapted to engage with an adjacent member of the *oxyrhina* or *apostrophe*.

3. In a fastening for frame and lens of glasses, the combination with the base and cover adapted to lie on opposite sides of the lens, of a cap-screw passing through one arm and the lens, and a screw passing through said sleeve and engaging the two arms to bind them upon the lens.

Chain.—An interlock on the sides of a comb-frame or bedstead, for the purpose of connecting the sides with the slats, which said interlock is a part of the same piece as the sides themselves, and consists of two points or catches facing each other, for receiving the ends of the slats, in com-

Claim.—1. In a machine for pressing plastic material, disc therefor, die-operating means, a fulcrum for the die-operating means, a cushioned journal-block for said means and means for adjusting said block to adjust the fulcrum to regulate the throw of the disc.

2. Is a machine for pressing plastic material, a pair of dies thereby, means for operating said dies toward or away from each other, a cushioned journal-block for said means, an adjustable fulcrum for the die-operating means for regulating the throw of said dies, and means for operating one of said dies at a different speed from the other die and independent of each other.

3. In a machine for pressing plastic material, dies therefor, means for operating said dies toward or away from each other, an adjustable fulcrum for said means, and a cushioning device for one of said dies out of contact with said dies and at a distance from the position of the stroke of said dies.

4. In a machine for pressing plastic material, means for operating the die toward and away from each other, a combined journal-block for said means, the die, and means for adjusting the fulcrum of the said means and disconnected from the die-carrier, for adjusting the throw of one of said die.

5. In a machine for pressing plastic material, die therefor, means having an adjustable fulcrum for operating said die toward or away from each other, means acting directly on said operating means independent of the die-carriers for regulating the throw of the die, and means for moving the material to be pressed, between said die.

6. In a machine for pressing plastic material, a pair of dies therefor, means having an adjustable fulcrum for operating the same toward and away from each other, means acting directly on said operating means and disconnected from the disconnector for regulating the throw of said means and thereby the dies, means for guiding the material between said dies and means for removing the material from between said dies after the said material has been pressed.

7. In a machine for pressing plastic material, a pair of dies there-
for means for operating the same toward or away from each other and

U. S. PATENT OFFICE

8. In a machine for pressing plastic material, a pair of dies therefore, means for operating the same toward or away from each other, means for delivering the material to said dies, and a stop for preventing the material from passing said dies, and means movable with said stop for moving the unpressed material to a carrier.

9. In a machine for pressing plastic material, a pair of dies therefore, means for operating the same toward or away from each other, means having an adjustable fulcrum for operating one of said dies at a different speed from the other and a member on one of said dies for adjusting the pressure on the material.

10. In a machine for pressing plastic material, a pair of dies therefor, means for operating the same toward or away from each other, means for delivering the material between said dies, means for maintaining said material and means acting directly on said operating means independent of the die-carriers for adjusting the throw of one of said dies to prevent unnecessary pressing of said material.

"11. In a machine for pressing plastic material, a pair of dies therefor, means for operating said dies toward or away from each other, means acting directly on said operating means independent of the die-carriers for adjusting the throw of the dies, means for delivering the material to said dies and a device operated by the movement of one of said dies to remove the pressed material and to prevent the delivered material from passing said dies.

12. In a machine for pressing plastic material, a pair of dies thereon, means for operating said dies toward or away from each other, means acting directly on the said operating means independent of the dis-arranging for adjusting the throw of the dies, means for delivering the material to said dies, means for removing the pressed material and carrying same disposed at substantially right angles thereto for preventing the delivered material from passing the dies, and a belt adapted to receive the pressed material and carry the same to a desired point.

13. In a machine for pressing plastic material, a pair of dies therefor, means for imparting movement to one of said dies, a cushioned journal-block for said means, a lever for imparting movement to the other die and means for adjusting the fulcrum of said lever whereby the thrust of the die is adjusted.

14. In a machine for pressing plastic material, a pair of dies therefor, means for imparting motion to one of said dies, a lever adapted to impart motion of a quicker nature to the other die, and a combining device carried by said lever at a distance from the position of the stroke of the die whereby increasing number of said material is prevented.

15. In a machine for pressing plastic material, a pair of dies therefor, means for imparting motion to said dies toward and away from one another, means for varying the thickness of said means for regulating the throw of the dies, a step normally out of the path of movement of the material, means carried with one of said dies for moving said step into the path of movement and means for returning said step to its normal position.

701,114. COUPLING AND NIPPLE FOR OUTLET OR JUNCTION BOXES. MORRIS F. WILSON, Brighton, Mass. Filed Feb. 2, 1922. Serial No. 92,242. (No model.)

Claim.—1. An integrally-formed coupling and nipple for uniting of junction boxes having other than round holes, consisting of a tubular body having a wall-engaging and portion adapted to project through said holes, substantially as described.

2. An integrally formed coupling and nipple for outlet or junction boxes having other than round holes, consisting of a tubular cylindrical body having an end portion adapted to project through said holes as provided with wall-receiving grooves or recesses, substantially as described.

8. An integrally-formed coupling and nipple for outlet or junction boxes having other than round holes, consisting of a tubular cylindrical body having an end portion adapted to project through said holes or provided with well-ventilated grooves or recesses provided with well-known closures, substantially as described.

4. An integrally-formed coupling and nipple for outlet or junction boxes having other than round holes, consisting of a tubular cylindrical body having an end portion adapted to project through said holes and provided with wall-receiving grooves or recesses, the sides of which converge to reduce the width of said grooves or recesses and thereby produce wall-embedding portions, substantially as described.

5. An integrally-formed coupling and nipple for offset or junction boxes having other than round boxes, consisting of a tubular cylindrical body and a neck of larger diameter having laterally-projecting wall-engaging portions, substantially as described.

6. An integrally-formed coupling and nipple for outlet or junction boxes having other than round holes, consisting of a tubular cylindrical body and a neck of lesser diameter having laterally-projecting wall-engaging portions provided with inclined wall-engaging faces, substantially as described.

701,115. DRILLING MACHINERY. CHAMBERLAIN, Louisville, Ky. Filed July 6, 1909. Serial No. 22,674. (No model.)

Claim.—1. In a drill, the combination with a support, a hand movably mounted thereon, and a revolvable spindle carried by said hand, of a motor mounted within said hand, and carried thereby, the drive-shaft of said motor being arranged horizontally and located between said support and said revolvable spindle, a pinion carried by said drive-shaft, bevel-gear driven by said pinion, a bevel-gear connected to said bevel-gearing, a vertical shaft, a bevel-gear on said vertical shaft and driven by first-mentioned bevel-gear, a pinion on said vertical shaft, and a gear-wheel having a spiral connection with the said revolvable spindle, and in engagement with said pinion.

2. In a drill, the combination with a support, a hand screwly secured thereto, and a revolvable spindle carried by said hand, of a motor mounted within said hand, and carried thereby, the drive-shaft of said motor being arranged horizontally and located between said support and said revolvable spindle, a pinion carried by said drive-shaft, beak gearing driven by said pinion, a bevel-gear connected to said beak gearing, a vertical shaft, a bevel-gear on said vertical shaft and driven by first-named bevel-gear, a pinion on said vertical shaft, a gear-wheel having splined connection with the said revolvable spindle, and in engagement with said pinion, and means for imparting a longitudinal movement to said spindle, driven from said vertical shaft.

3. Is a drill, the composition, with a support, a head movably secured thereto, and a revolvable spindle carried by said head, of a motor carried by said head and having a horizontal driving-shaft, a gear having a splined connection with the spindle, and gearing for transmitting motion from the motor to said spindle-gear, and including bevel-gears and

a vertical shaft driven thereby and carrying a gear intermeshing with said spindle-gear.

4. In a drill, the combination, with a support, a head movably secured thereto, and a revolvable spindle carried by said head, of a motor carried by said head and having a horizontal driving-shaft, a gear having a spiral connection with the spindle, gearing for transmitting motion from the motor to said spindle-gear, and including bevel-gears and a vertical shaft driven thereby and carrying a gear intermeshing with said spindle-gear, and automatic feed appliances driven from said motor-shaft.

701,116. MACHINE FOR MAKING BUTTRES. JOHN E. WILLIAMS, St. Louis, Mo., assignor to E. A. Hyatt, St. Louis, Mo. Filed June 26, 1901. Serial No. 68,178. (No model.)

Claim.—1. In a buttress-forming machine, a rotatable base; a die mounted upon the base; a standard revolvable to the base; a plunger carried by the standard in position to swing from one die to another; a die loosely mounted upon said plunger, there being an L-slot in the plunger and a pin extending from the die into said slot, said die being locked on the plunger when rotated to move the pin into the horizontal part of the slot and said die being free to slide on the plunger when unlocked; an arm projecting from said plunger-die; and steps mounted upon the base in position to be engaged by said arm, as required to rotate said plunger-die upon the plunger by the swinging of the plunger from one die to another, thereby alternately locking and unlocking said die; substantially as specified.

2. In a buttress-forming machine, a rotatable base; two dies mounted upon the base; a standard revolvable to the base; a plunger mounted in the standard in position to be swung from one die to the other; adjustable steps mounted upon the base to limit the swing of said standard, as required to bring the plunger exactly in position over said fixed dies; an arm extending from the standard between said steps, so that the plunger may be adjusted independently relative to each die; and a handle for operating said plunger, substantially as specified.

3. In a buttress-forming machine, a rotatable base; dies mounted upon the base; a standard revolvable to the base; a plunger carried by the standard in position to swing from one die to another; a die loosely mounted upon said plunger, there being an L-slot in the plunger and a pin extending from the die into said slot, said die being locked on the plunger when rotated to move the pin into the horizontal part of the slot and said die being free to slide on the plunger when unlocked; an arm projecting from said plunger-die; and steps mounted upon the base in position to be engaged by said arm, as required to rotate said plunger-die upon the plunger by the swinging of the plunger from one die to another, thereby alternately locking and unlocking said die; adjustable steps mounted upon the base to limit the swing of said standard, as required to bring the plunger exactly in position over said fixed dies; and a handle for operating said plunger, substantially as specified.

701,117. JAR-GLASS. HANS J. WITTMANN, Omaha, Neb. Filed June 1, 1901. Serial No. 68,708. (No model.)

Claim.—A shoulder comprising a recessed cover, a flange at the edge thereof adapted to bear upon the neck of a bottle, said shoulder within

the recess, a cross-head mounted thereon, a vertically-movable pin extending through the cross-head and cover, a concave-convex expanding-disk secured to the pin, an inclined rim to said disk, strengthening-ribs thereon, an annular flange at the edge of said disk, and a gasket interposed between and adapted to be compressed by the flanges of the cover and disk, said inclined rim serving to expand the gasket.

701,118. WEB-CONTROLLING MECHANISM. HENRY A. W. WOOD, New York, N. Y., assignor to the Campbell Printing Press & Manufacturing Company, New York, N. Y., a Corporation of New York. Filed Mar. 4, 1902. Renewed Oct. 12, 1901. Serial No. 73,008. (No model.)

Claim.—1. The combination in a web-printing press of a web-roll, with a pump actuated therefrom, serving as a controller or brake for the web-roll, said pump being arranged to pump an incompressible liquid.

2. The combination in a web-printing press of the web-roll, a pump actuated therefrom, and arranged to pump an incompressible liquid, and means for controlling the resistance against which the pump has to work to regulate or control the motion of the web-roll.

3. The combination in a web-printing press of the web-roll, a pump actuated therefrom, and arranged to pump an incompressible liquid, and means for controlling the direction of the pump to regulate or control the motion of the web-roll.

4. The combination in a web-printing press of the web-roll, a pump actuated therefrom, and arranged to pump an incompressible liquid, a circulating-line connected therewith, and a valve arranged in said line.

5. The combination in a web-printing press of a pump secured thereto, and arranged to pump an incompressible liquid, the shaft of the web-roll and means for connecting the same to the pump.

6. The combination in a web-printing press of the shaft carrying the web-roll, said shaft being shabbled at its end, a pump, a shaft arranged to actuate the pump, this shaft being shabbled to fit the shabbled end of the web-roll shaft, and a coupling for sliding over the shabbled ends of the shafts to couple said shafts together.

7. The combination in a web-printing press of the web-roll, a pump arranged to pump an incompressible liquid actuated therefrom and serving as a controller or brake for the web-roll, and a valve arranged to connect the direction with the induction of the pump so that the web-roll can be easily turned and the web driven therefrom to thread the machine.

8. The combination in a web-printing press of the web-roll, a pump arranged to pump an incompressible liquid actuated therefrom and serving as a controller or brake for the web-roll, means for closing the induction of the pump and a relief-valve arranged between the induction and induction of the pump.

9. The combination in a web-printing press of the web-roll, a pump arranged to pump an incompressible liquid actuated therefrom and serving as a controller or brake for the web-roll, a regulating-valve controlling the resistance of the pump, and means for operating said regulating-valve from the tension of the web.

10. The combination in a web-printing press of the web-roll, a pump arranged to pump an incompressible liquid actuated therefrom and serving as a controller or brake for the web-roll, a spring-actuated regulating-valve for controlling the resistance against which the pump has to work, and connections for operating this valve from the tension of the web.

11. The combination in a web-printing press of the web-roll, a pump arranged to pump an incompressible liquid actuated therefrom and serving as a controller or brake for the web-roll, a valve controlling the resistance against which the pump has to work, a movable roll bearing on the web, and connections from the roll to the valve.

12. The combination in a web-printing press of the web-roll, a pump arranged to pump an incompressible liquid actuated therefrom and serving as a controller or brake for the web-roll, a drawing device for drawing the web from the web-roll, and a valve controlling the resistance against which the pump has to work.

13. The combination in a web-printing press of the web-roll, a pump arranged to pump an incompressible liquid actuated therefrom and serving as a controller or brake for the web-roll, a stop-valve controlling the action of the pump, and connections whereby when the web breaks, the stop-valve will be closed.

14. The combination in a web-printing press of a web-roll, a pump arranged to pump an incompressible liquid actuated therefrom and serving as a controller or brake for the web-roll, a stop-valve controlling the action of the pump, a roller bearing on the web, and connections between the roller and the stop-valve.

15. The combination in a web-printing press of the web-roll, a pump arranged to pump an incompressible liquid actuated therefrom and serving as a controller or brake for the web-roll, a stop-valve having a weight tending to normally close the same, a roll bearing on the web and holding said valve normally open, and connections from the roll to the valve whereby when the web breaks, the valve will automatically close and stop the pump.

16. The combination in a web-printing press of the web-roll, a pump arranged to pump an incompressible liquid actuated therefrom and serving as a controller or brake for the web-roll, and a plurality of stop-valves with connections to stop the pump in case the web breaks.

17. The combination in a web-printing press of a web-roll, a pump arranged to pump an incompressible liquid actuated therefrom and serving as a controller or brake for the web-roll, and a hand-valve arranged at a point remote from the web-roll controlling the resistance of the pump, whereby the motion of the web-roll may be controlled at a point remote from the same.

18. The combination in a web-printing press of a web-roll, a pump arranged to pump an incompressible liquid actuated therefrom and serving both as a controller or brake for the web-roll, a valve controlling the resistance against which the pump has to work, a movable roller bearing on the web, connections from the roller to the valve, a stop-valve arranged in the induction of the pump, another roller bearing on the web, and connections whereby this roll connects to the stop-valve, whereby the first-named roller will act to properly tension the web-roll, and the second-named roller will act to stop the web-roll if the web breaks.

19. The combination of a web-roll, a rotary pump actuated therefrom to serve as a brake for the web-roll, said pump being arranged to pump an incompressible liquid through a circulating system, and a valve in said system for varying the resistance against which said rotary pump has to work.

701,119. INKING APPARATUS. HENRY A. W. WOOD, New York, N. Y., assignor to the Campbell Printing Press & Manufacturing Company, New York, N. Y., a Corporation of New York. Filed Mar. 4, 1902. Renewed Oct. 12, 1901. Serial No. 73,009. (No model.)

Claim.—1. The combination with an ink-supply, a rotating duster taking ink from the roller thereof, and means for positively turning the duster on its axis so that the same will roll over the surface of the supply-roller.

2. The combination with an ink-supply, rotating dusters taking ink from the roller thereof, and means for continuously and positively turning the dusters so that the same will roll over the surface of the supply-roller.

3. The combination with an ink-supply, an orbitally-rotating duster taking ink from the roller thereof, and a receiving-roller in constant engagement with the duster-roller.

4. The combination with an ink-supply, orbitally-rotating dusters taking ink from the roller thereof, and a receiving-roller in constant contact with each of the dusters.

5. The combination with an ink-supply, a duster taking ink from the roller thereof, a receiving-roller in constant contact with the duster, and means for orbitally rotating the duster and receiving-roller.

6. The combination with an ink-supply, dusters taking ink from the roller thereof, a receiving-roller in constant contact with each of the dusters, and means for orbitally rotating the dusters and receiving-roller.

7. The combination with an ink-supply, a duster, a receiving-roller in engagement with the duster, a roller as M, and means for orbitally rotating the receiving-roller and duster.

8. The combination with an ink-supply, a plurality of dusters, a receiving-roller in engagement with each duster, a roller as M, and means for orbitally rotating the dusters and receiving-roller.

9. The combination with an ink-supply, a duster, a receiving-roller in engagement with the duster, a roller as M, means for rotating the receiving-roller and duster, and means for moving the duster about the axis of the receiving-roller during its rotation.

10. The combination with an ink-supply, a plurality of dusters, a receiving-roller in engagement with each duster, a roller as M, means for rotating the dusters and receiving-roller, and means for moving the dusters about the axis of their respective receiving-rollers during their rotation.

11. The combination with an ink-supply, a duster, a receiving-roller in engagement with the duster, a rotating roller as M, means for axially rotating the duster and receiving-roller, and means for orbitally rotating the duster and receiving-roller so proportioned and arranged that the duster will roll over the roller of the fountain, and so that the receiving-roller will engage the roller M and rotate therewith.

12. The combination with an ink-supply, a plurality of dusters, a receiving-roller in engagement with each duster, a rotating roller as M, means for rotating the dusters and receiving-roller, and means for turning the dusters and receiving-roller upon their axes, so proportioned and arranged that the dusters will roll over the fountain-roller and so that the receiving-roller will engage the roller M, and rotate therewith.

13. The combination with an ink-supply, a receiving-roller, arms mounted concentrically therewith and carrying a duster-roller, means for rotating the receiving-roller and the duster, a roller as M, and means for moving the duster to engage the roller of the fountain and to clear the roller M, consisting of grooved disks, and rollers mounted on said arms engaging said disks.

14. The combination with an ink-supply, a plurality of receiving-roller, a duster in engagement with each receiving-roller, and mounted in arms journaled concentrically to the axis of each receiving-roller, means for rotating the receiving-rollers and dusters, a roller as M, and means for moving the dusters to engage the roller of the fountain and to clear the roller M, consisting of grooved disks, and rollers arranged on said arms engaging said disks.

15. The combination with an ink-supply, a duster and receiving-roller bearing on each other, a gear on the receiving-roller, a pinion engaging the same, means for rotating the duster-roller, receiving-roller and pinion, and a stationary internal gear with which said pinion meshes, whereby the duster-roller and the receiving-roller will be turned upon their axes as the same are rotated.

16. The combination with an ink-supply, a plurality of receiving-roller, a duster-roller in engagement with each of the receiving-roller, a gear on each receiving-roller, a pinion engaging the gear of each receiving-roller, means for rotating the dusters, receiving-rollers and pin-

less, and a stationary, internal gear with which said pinions mesh, whereby said duster-rollers and receiving-rollers will be turned on their axes as the same are rotated.

17. The combination with an ink-fountain, a receiving-roller and a duster-roller, means for rotating the same, gearing whereby said duster-roller and said receiving-roller will turn on their axes as they are rotated, a roller as M, and means for moving the fountain-roller and will clear the roller M.

18. The combination of an ink-fountain, a plurality of receiving-rollers, a duster engaging each receiving-roller, means for rotating the receiving-rollers and dusters, gearing whereby the receiving-rollers and dusters will turn on their axes as they are rotated, a roller as M, and means for moving the dusters in their rotation so that they will engage the fountain-roller and clear the roller M.

701,190. DOUBLES MULTIPRESS. HENRY A. W. WOOD, New York, N. Y. Filed Feb. 25, 1900. Serial No. 6,998. (No model.)

Claim.—1. The combination of two flat-bed traveling-impression-cylinder web-perforating printing-presses arranged one over the other, web-guides arranged so that two webs can be led through the mechanism, and devices for associating the two webs after they are perforated.

2. The combination of two side frames, four form-beds mounted therein in different horizontal planes, two sets of carriers fitted to said frames, each set carrying two impression-cylinders and web-guides, mechanism for reciprocating the two sets of carriers, web-guides for leading two webs through the machine, and manipulating devices for shifting said webs around the cylinders during the non-impression periods.

3. The combination in a web-perforating printing-press of four form-beds arranged in different horizontal planes, a traveling impression-cylinder cooperating with each form-bed, web-guides arranged so that a web may be led around the lower and upper cylinders, and another web around the second and third cylinders, and a suitable web-manipulating device for each web.

4. The combination in a web-perforating printing-press of four form-beds arranged in different horizontal planes, a traveling impression-cylinder cooperating with each form-bed, web-guides arranged so that a web may be led around the lower and upper cylinders, and another web around the second and third cylinders, whereby the last-named web is substantially within the loop of the first-named web, a suitable web-manipulating device for each web, and devices for associating the two webs.

5. The combination of two flat-bed traveling-impression-cylinder web-perforating printing-presses arranged one over the other, web-guides arranged so that one or two webs can be led through the mechanism, and means whereby one or both presses may be operated.

6. The combination in a web-perforating printing-press of four form-beds arranged in different horizontal planes, a traveling impression-cylinder cooperating with each form-bed, web-guides arranged so that one or two webs may be led through the mechanism, two driving mechanisms, one arranged to reciprocate the two lower and the other the two upper cylinders, and connection whereby one driving mechanism can be thrown out of operation.

7. The combination in a web-perforating printing-press of four form-

beds arranged in different horizontal planes, two sets of carriers, each set carrying two impression-cylinders, a driving mechanism for each set of carriers, web-guides arranged so that one or two webs may be led through the mechanism, web-manipulating mechanisms, and connections whereby only one set of carriers can be operated.

8. The combination in a web-perforating printing-press of four form-beds arranged in different horizontal planes, a traveling impression-cylinder cooperating with each form-bed, web-guides arranged so that a web may be led around the lower and upper cylinders, and another web around the second and third cylinders, a feeding-in and feeding-out device for each of these webs, and means whereby the feeding-in device for the second web may be used as the feeding-out device when only one web is run through the machine, whereby the two lower impression-cylinders may be used for handling a single web.

701,191. STOCK OR POULTRY FEEDING DEVICE. ZACHARIAH LEVER, Santa Cruz, Cal. Filed Aug. 22, 1901. Serial No. 73,964. (No model.)

Claim.—1. The combination of a hopper with a bottom plate having a feed-opening, and attachable on the lower end of a hopper, of a feeding device for discharge of feed from the hopper and slidable at the opening, a swinging bar controlling the feeding device, and means to secure and protect bait at the lower end of the swinging bar for movement by a fowl or animal.

2. The combination with a supported hopper having a feed-opening in the bottom, of a swinging bar, a chute or gate slidable at the opening and controlled by the swinging bar, and means to secure and protect bait at the lower end of said bar for movement by a fowl or animal.

3. The combination with a supported hopper having a feed-opening in the bottom wall, of a rockable bar, a gate or chute in the hopper adapted for longitudinal movement by the movement of the bar, a hood in the hopper over the feed-opening, and a device for holding and protecting bait at the lower end of the bar adapted for movement by a fowl or animal.

4. The combination with a supported hopper having a feed-opening in the bottom wall, of a rockable bar extending up through the feed-opening, a gate or chute in the hopper and through which the bar passes, a bait-box on the lower portion of the bar, and a cap on the bait-box protected by and projecting laterally therefrom, a perforated lid, the lid including a fowl or animal to move the bar and discharge feed.

5. The combination with a supported hopper having a feed-opening in the bottom wall, an arched hood over said opening, and a swing rod or bar hung from the hood, of a gate or chute held to slide near the feed-opening and through which the bar passes, and a bait-box projecting laterally from the swing-rod and having a cup protected by a perforated lid, for movement by a fowl or animal.

6. The combination with a hopper, legs on said hopper, guides on the bottom of the hopper at each side of a feed-opening therein, and a gate or chute held to slide between the guides at the feed-opening, of an upright rod or bar adapted to swing in the feed-opening, a device adapted to control the swinging movement of the rod or bar, and means for attaching and protecting a bait on the lower part of the rod or bar for movement by a fowl or animal that endeavors to get the bait.

7. The combination with a hopper, legs on the hopper, guides on the bottom of the hopper at each side of a feed-opening therein, and a hood over said feed-opening, of a gate or chute held to slide at the feed-

opening by a loose engagement with the guides, a rod or bar pendant through the feed-opening and also through a perforation in the chute or gate, and having a loose engagement with the hood, a bracket-supported check-bar hung from the hopper and adapted to control the swinging movement of the pendant rod or bar, and a bait-holding device projecting laterally from the lower portion of the rod or bar, adapted to be moved with said bar by efforts of a fowl or animal to get the bait.

8. In a poultry-feeder, the combination with a suitable container, of a reciprocating valve-slide confined on the bottom of said container, and arranged to traverse a discharge-opening therein, a vertical swinging bar mounted to turn on a horizontal axis and operatively connected with said valve to actuate the latter, and means carried by said bar to serve as a support for a fowl and adapted to receive a bait, whereby the weight of a fowl perched on the bar is adapted to impart movement thereto and to the valve-slide.

701,192. COMBINED LIGHTNING-ARRESTER AND FEEDING-POST. HENRY R. YALLEY, Chicago, Ill., assignor to American Electric Telephone Company, Chicago, Ill., a Corporation of New Jersey. Filed Mar. 13, 1901. Serial No. 59,922. (No model.)

Claim.—1. A lightning-arrester comprising three combined carbon-holders and blinding-posts, each post having a transverse opening, three carbons held end to end in said openings and arranged in line, the head of each post being provided with a screw-threaded member for securing a wire in place.

2. A lightning-arrester comprising a plurality of combined carbon-holders and blinding-posts, each post being formed with a base and a head and also with an enlarged middle or intermediate portion having a transverse opening, adjustable carbons held end to end in said openings and arranged in line, the head of each post being provided with a screw-threaded member for securing a wire in place.

3. The combination of three metal posts having their bases secured to a support and arranged close together in a row, a cylindrical piece of carbon extending transversely through the middle portion of each post, the three carbons thus arranged end to end in a line being capable of unlimited endwise adjustment in either direction, and screw-threaded members mounted upon the heads of said posts and adapted for securing wires in place.

4. A lightning-arrester comprising three metal posts having their bases secured to a support and arranged close together in a row, each post being provided with a transverse opening, three carbons held end to end in said openings and arranged in line, said carbons being capable of unlimited endwise adjustment in either direction, means holding the carbons in place, a screw-threaded member for connecting the middle post with a grounded conductor, and screw-threaded members for connecting the outside posts with the direct-conductor.

5. A lightning-arrester for use in connection with a subscriber's telephone set, consisting of three blinding-posts having their bases secured to a suitable support, each blinding-post being provided with a transversely-extending socket or opening, the said blinding-posts being arranged in a row with their said openings or sockets in line, cylindrical pieces of carbon mounted in said sockets or openings and held end to end, cut-overs for holding the carbons in place, the free end of each blinding-post being provided with a relatively small transverse opening adapted to receive a wire, and also with a longitudinally-extending cut-over for holding a wire in said relatively small opening.

701,193. BURNER. HENRY C. SMITH, New York, N. Y. Filed Mar. 3, 1901. Serial No. 58,595. (No model.)

Claim.—1. A burner having a mixing-chamber provided with a vertical and a horizontal member, the vertical member being open at its lower end to the atmosphere and having a gas-inlet, a burner-tip connected with the top of said mixing-chamber, a heating or combustion chamber surrounding the burner-tip and having air-inlets separate from the air-inlets of the mixing-chamber, and means for supporting the mixing-chamber from the heating-chamber and holding the same in contact therewith, as set forth.

2. A burner having a mixing-chamber provided with air and gas inlets and having a vertical and a horizontal member, a burner-tip connected with said mixing-chamber, a heating or combustion chamber surrounding the burner-tip and having air-inlets separate from the air-inlets of the mixing-chamber, and means for supporting the mixing-chamber from the heating-chamber and holding the same in contact therewith, as set forth.

mixing-chamber, and an auxiliary tip connected with the horizontal member of said mixing-chamber and extending in the heating or combustion chamber, as set forth.

3. A burner having a mixing-chamber provided with air and gas inlets and formed with a vertical member and a horizontal member, a burner-tip connected with said mixing-chamber, a heating or combustion chamber surrounding the burner-tip and having air-inlets separate from the air-inlets of the mixing-chamber, and an auxiliary tip connected with the top of the horizontal member of said mixing-chamber and extending in the combustion-chamber, the upper end of said auxiliary tip reaching to the outlet of the combustion-chamber, as set forth.

4. The combination with a burner having a mixing-chamber provided with air and gas inlets, and a burner-tip connected with the top of the mixing-chamber and formed with a depending flange provided with notches, of a heating or combustion chamber surrounding the burner-tip, and having air-inlets separate from the air-inlets of the mixing-chamber, and a receptacle for the material to be heated, the said receptacle forming the top of the heating or combustion chamber, as set forth.

5. The combination with a burner having a mixing-chamber provided with air and gas inlets, and a burner-tip connected with said mixing-chamber, of a heating or combustion chamber surrounding the burner-tip and having air-inlets separate from the air-inlets of the mixing-chamber, and a receptacle for the material to be heated, said top plate having an annular upwardly-extending rim for direct engagement with the bottom of the heating-chamber, the top plate also having a flange depending from the outer side and within which extends the upper end of the mixing-chamber, as set forth.

6. A burner having a top plate provided with a rim, a heating or combustion chamber against the bottom of which the rim of the top plate is adapted to engage, and a spring having its ends extending upward and engaging respectively the heating-chamber and the top plate of the burner for supporting the latter and holding the rim in contact with the under side of the heating-chamber, as set forth.

7. A burner having a mixing-chamber provided with an air-inlet and connected with a gas-supply, a top plate for said mixing-chamber and extending beyond the same, the top plate having a depending flange adapted to receive the upper end of the mixing-chamber, the extended portion of the top plate having air-inlet openings, and a burner-tip on the upper surface of the top plate and connected with said mixing-chamber the said burner-tip fitting within a correspondingly-shaped flange on the top plate, as set forth.

8. A burner, comprising a heating or combustion chamber, having an opening therein, an apertured top plate having a rim fitting the under side of the heating-chamber around the opening, the said top plate having a depending flange on its under face, a burner-tip on the upper surface of the top plate, and a mixing-chamber having a vertical member open at its lower end to the atmosphere and provided with a gas-inlet and a horizontal member extending from the upper portion of the vertical member, the said mixing-chamber being connected with the burner-tip by apertures in the top plate, the upper end of the mixing-chamber fitting within the depending flange on the top plate, as set forth.

9. The combination with a heating or combustion chamber having an opening in its bottom, of a burner having a top plate carrying a burner-tip and provided with a rim fitting the under side of the heating-chamber around the opening, and springs engaging legs on the burner and the heating-chamber for connecting the burner with said heating-chamber and for holding the rim of the top plate in firm contact with the under side of the heating-chamber, as set forth.

10. The combination with a heating-chamber provided in its under side with depending legs, of a burner having a top plate arranged to engage the under side of the heating-chamber, the top plate being also pro-

vided with depending legs, and springs engaging the legs of the heating-chamber and the said top plate, as set forth.

11. The combination with a heating-chamber, of a burner engaging the under side of the heating-chamber, and a heat spring coiled at the head and having its members extending upward and connected respectively with the heating-chamber and the burner to hold the burner against the heating-chamber, as set forth.

12. The combination with a heating-chamber provided on its under face with depending legs, of a burner on the under side of the heating-chamber and also provided with legs in horizontal alignment with the legs on the heating-chamber, and springs engaging the legs to hold the burner against the heating-chamber, as set forth.

13. A burner, comprising a mixing-chamber having a vertical member open at its lower end to the atmosphere, and provided near said lower end with a gas-inlet extending upward and downward through the wall of said vertical member, a top plate for said mixing-chamber provided with an upwardly-extending rim, and a burner-tip on the top plate within said rim and connected with the mixing-chamber, the said burner-tip having a depending flange provided with notches and engaging a correspondingly-shaped flange on the top plate, as set forth.

14. A burner, comprising a mixing-chamber having a vertical member and an approximately horizontal member, the vertical member being open at its lower end to the atmosphere, and provided near said lower end with a gas-inlet adapted for connection with a gas-supply pipe, a top plate for the mixing-chamber and extending beyond the same, the top plate having an integral depending flange adapted to receive the upper end of the mixing-chamber, a burner-tip on the top plate and connected by apertures in the top plate with the mixing-chamber, the extended portion of said top plate being also provided with apertures, and an upwardly-extending auxiliary tip connected with the horizontal member of the mixing-chamber near the end thereof, as set forth.

701,124. VAGINAL SYRINGER. CHARLES F. ALLEN, HUSBAND. Cal. Filed May 27, 1901. Serial No. 65,127. (No model.)

Claim.—1. A vaginal syringe, consisting of a rigid frame comprising a front plate provided with a marginal head, a tubular inlet-stem, and a drain-outlet, and a body of flexible material terminating in an apertured tip of greater thickness than the material of the body, the said body being of conical shape, the forward end of the body being arranged to be sprung over the marginal head of the front plate, as described.

2. In a vaginal syringe, a frame comprising a front plate, a tubular stem extending through the front plate to a distance beyond the rear thereof, the rear portion of the stem being curved, and a drain-pipe which passes through the said plate, and a conical body of flexible material, provided with a tip also of flexible material but of greater thickness than the body, which tip is closed at its rear end and is in communication with the inner or rear end of the tubular stem, the tip having an upward curve, being provided with series of apertures, the body being likewise provided with apertures, and means substantially as described, for detachably attaching the said body to the front plate of the frame.

3. In a vaginal syringe, the combination, with a frame, consisting of a front plate, an upwardly-curved tubular stem extending from the rear portion of the front plate, and a drain-pipe extending outward from the said front plate, of a body constructed of flexible material and having a conical shape, the forward end of the body being in frictional engagement with the peripheral portion of the plate of the frame, an upwardly-curved apertured tip formed integral with the inner or rear end of the said body, the material of the tip being of greater thickness than the material of the body, the rear or inner end of the tip being closed and its forward end in communication with the said tubular stem and the body being provided with apertures adjacent to the forward end of the said tip, as described.

4. In a vaginal syringe, the combination, with a frame, consisting of a front plate provided with a marginal head, an upwardly-curved tubular stem extending from the rear portion of the front plate and provided with a collar near its rear end, and a drain-pipe extending outward from the said front plate, of a body constructed of flexible material and having a conical shape, the forward end of the body being arranged to be sprung over the head of the front plate and having a marginal rib adapted to en-

gage with the outer face of the plate within the line of the marginal head, an upwardly-curved apertured tip formed integral with the inner or rear end of the said body, the material of the tip being of greater thickness than the material of the body, the rear or inner end of the tip being closed and its forward end in communication with the said tubular stem, and the body being provided with apertures adjacent to the forward end of the said tip, for the purpose set forth.

701,125. PROCESS OF MAKING RUBIN SIZE. FRIEDRICH ALBRECHT, New York, N.Y., and HERMAN ALBRECHT, Garsden, England. Filed Jan. 26, 1902. Serial No. 91,202. (No specimens.)

Claim.—1. The process herein described of making rubin size, which consists in mixing an oil or fat with a suitable molten resin, filtering the mixture, adding to the same a solution of an ammonium compound and an alkali lye, the latter in sufficient quantity to induce saponification, and agitating the resulting mixture in contact with carbonic acid gas under conditions permitting saponification of only a portion of the resin, substantially as set forth.

2. The process herein described of making rubin size, which consists in mixing an oil or fat with a suitable molten resin, filtering the mixture, adding to the same a solution of an ammonium compound and an alkali lye, the latter in sufficient quantity to induce saponification, and agitating the resulting mixture in contact with carbonic acid gas and under such heat and pressure as to permit saponification of only a portion of the resin, substantially as set forth.

3. A rubin size containing free compressed resin, free alkali and an ammonium resinate, substantially as set forth.

701,126. TEST. FRIEDRICH ALBRECHT, Berlin, Germany. Filed Mar. 1, 1902. Serial No. 85,202. (No model.)

Claim.—1. In a sliding test, longitudinally-recessed frame-posts, rods fitting into the recesses and holding the ends of the test-walls, and adjustable means for retaining said rods in the recesses, all substantially as and for the purpose herein set forth.

2. In a sliding test, longitudinally-recessed frame-posts, rods fitting into the recesses and holding the ends of the test-walls, and clip-bolts passing

ing through said posts and retaining the rods in said recesses, all substantially as and for the purpose herein set forth.

701,127. FLOW. GEORGE R. BARTY, Bellville Park, Minn. Filed June 12, 1901. Serial No. 84,712. (No model.)

Claim.—1. A wheeled plow, comprising crank-shafts, a standard loosely mounted on the crank-shafts and provided with a reduced shank at its lower end, a shovel provided with a head and mounted so as to turn on the lower end of the standard, means for limiting the turning movement of the shovel in both directions, a coil-spring encircling the standard for holding the shovel in its operative position, means for swinging or tilting the shovel, and a spring-dog for locking the shovel in its inoperative position.

2. In a wheeled plow, the combination with the main frame and carrying-wheels, of a plurality of crank-shafts mounted one above the other and adapted to rotate in opposite directions, a standard journaled on the lower crank-shaft and provided in its upper portion with a longitudinal slot in which is received the upper crank-shaft, and a spring-actuated oscillatory shovel mounted on the lower end of the standard.

3. In a wheeled plow, the combination with the main frame and carrying-wheels, of a plurality of crank-shafts, a series of standards actuated thereby and provided with reduced shanks at their lower ends, a shovel provided with a head journaled on the lower end of each standard, means for limiting the turning movement of the shovel in both directions, a coil-spring encircling each standard for holding the shovel in its operative position, means on the frame for swinging or tilting the shovel, and spring-dogs for locking each shovel in its inoperative position.

4. In a wheeled plow, the combination with the main frame and carrying-wheels, of a plurality of crank-shafts, a series of standards actuated thereby, a shovel provided with a head rotatable axially on the lower end of each standard, a flange on said head having a projecting portion, deflecting devices on the main frame adapted to cooperate with said projecting portion of the flanges for turning the shovels, and retracting springs on the shovels for returning the shovels to their operative positions.

5. In a wheeled plow, the combination with the main frame and carrying-wheels, of a plurality of crank-shafts, a series of standards actuated thereby, shovels mounted to turn axially on the lower ends of the standards, and a series of combined deflectors and scrapers connected to the main frame and arranged in the path of the shovels whereby the shovels are successively oscillated and scraped.

6. In a wheeled plow, the combination with the main frame and carrying-wheels, of a plurality of crank-shafts, a series of standards actuated thereby, a shovel having a head journaled axially upon the lower end of each standard, a spring for yieldingly holding each shovel in its

operative position, means for turning the shovels axially on the standards, a dog for locking each shovel after it has been turned, and a tripping device for disengaging the dog.

7. In a wheeled plow, the combination with the main frame and carrying-wheels, of a plurality of crank-shafts, a series of standards actuated thereby, a shovel having a head journaled axially on the lower end of each standard, springs for yieldingly holding the shovels at two limits of their throw, means on the frame for turning the shovel, a spring-dog for automatically locking the shovel at one limit of its throw, and a tripping device in the form of a rock-shaft having oppositely-projecting terminal cranks, one of which co-operates with the spring-dog, and the other with a part of the crank-shaft.

8. In a wheeled plow, the combination with the main frame and carrying-wheels, of a plurality of crank-shafts, a series of standards actuated thereby and provided with reduced shanks at their lower ends, a shovel provided with a head journaled on the lower end of each standard, a flange on said head, a projecting portion on each flange having a locking-notch, a spring-dog on each of said standards to engage said locking-notch at one limit of its throw, tripping devices for said dogs, and a spring coiled about the reduced portion of each standard and having one end fixed to the shovel-head and the opposite end to the standard for holding the shovel at one limit of its throw, and means on the frame for turning said shovel.

701,128. LIFE-SOAT. ADOLPH BAUMANN, Curacao, Nether. Filed June 4, 1901. Serial No. 83,164. (No model.)

Claim.—The combination in a boat of the character described of a main central chamber, a forward chamber, a narrow cylindrical communication between said forward and said main chambers, a rear chamber, a narrow cylindrical communication between said rear and said main chambers, a housing surrounding said main chamber provided with end disks working upon said cylindrical communication to form an air-chamber surrounding said main chamber, said housing and said disks being reversibly supported and held as and for the purpose set forth.

701,129. BOTTLE-WASHING MACHINE. WILIAM L. BULCHAP, Chicago, Ill., assignor to the Greenery Package Manufacturing Company, Chicago, Ill., a Corporation of Illinois. Filed May 11, 1902. Serial No. 14,217. (No model.)

Claim.—1. A bottle-washing apparatus, consisting of a tank having a partition dividing it into washing and rinsing compartments, a water-pipe arranged horizontally in the rear of the rinsing-compartment below the top thereof and provided with upwardly-directed nozzles, and a rack arranged to rest upon the top of the side walls of this rinsing-compartment and provided with apertures corresponding to the nozzles of the said water-pipe, substantially as described and for the purpose set forth.

2. A bottle-washing apparatus consisting of a tank having a vertical partition dividing it into washing and rinsing compartments, a water-

pipe extending into the rinsing-compartment and arranged horizontally in the same below the top thereof, the said pipe having upwardly-directed nozzles, a rack arranged to rest upon the top of the side walls of the rinsing-compartment and provided with apertures corresponding with said nozzles, supply-pipes 12 and 13 extending to the washing and rinsing compartments respectively; connection between the steam and water pipes and the supply-pipes 12 and 13, whereby either steam or water or both may be supplied at will to either or both of the compartments of the tank, a valve in the water-pipe outside of the rinsing-compartment, a valve-lever 10 for operating said valve, a link for operating the valve-lever, a spring tending to hold the valve-lever in such position as to normally close the valve, and a foot-lever for operating the link, substantially as described.

3. The combination with the tank, and a water-pipe therein having upwardly-directed nozzles, of a valve in said water-pipe, a lever for operating said valve, a spring tending to hold said lever normally in position to maintain the valve closed, a link 9 extending downwardly from the valve-lever, and a foot-lever 8 pivoted to the bottom of the tank and having its rear end connected with the link 9 and its forward end provided with a pedal for the foot, substantially as described.

701,180. APPARATUS FOR TESTING THE VOLUME OF AIR FROM THE LUNGS. MICHAEL BENEDICT, New York, N. Y. Filed July 28, 1901. Serial No. 68,347. (No model.)

Claim.—1. In an apparatus for testing the volume of the air blown from the lungs of a person, the combination, with a casing, of a series of gas-burners, gas-conveying pipes leading to the said burners, a series of gas-cocks, a bellows adapted to be expanded by forcing air into the same, and means for successively closing the said gas-cocks during the ascent of the bellows, substantially as and for the purposes set forth.

the bellows and opening the closed gas-cocks during the descent of the bellows, substantially as and for the purposes set forth.

2. In an apparatus for testing the volume of the air blown from the lungs of a person, the combination, with a casing, of a series of gas-burners, a stand-pipe, means for conducting gas into said stand-pipe, a series of gas-cocks connected with the said stand-pipe, a gas-conveying pipe between each gas-cock and each gas-burner, and means for successively closing and opening the said gas-cocks, substantially as and for the purposes set forth.

3. In an apparatus for testing the volume of the air blown from the lungs of a person, the combination, with a casing, of a series of gas-burners, a stand-pipe, means for conducting gas into said stand-pipe, a series of gas-cocks connected with the said stand-pipe, a gas-conveying pipe between each gas-cock and each gas-burner, a bellows adapted to be expanded by forcing air into the same, and means for successively closing the said gas-cocks during the ascent of the bellows, and opening the closed gas-cocks during the descent of the bellows, substantially as and for the purposes set forth.

4. In an apparatus for testing the volume of the air blown from the lungs of a person, the combination, with a casing, of a series of gas-burners, gas-conveying pipes leading to the said burners, a series of gas-cocks, an oscillating valve in each gas-cock provided with a forwardly-extending arm, a bellows adapted to be expanded by forcing air into the same, and means for successively engaging the forwardly-extending arms and thereby actuating the valves of said gas-cocks, consisting of a bracket having ribs adapted to engage with the said arms for closing or opening the said valves, substantially as and for the purposes set forth.

5. In an apparatus for testing the volume of the air blown from the lungs of a person, the combination, with a casing, of a series of gas-burners, gas-conveying pipes leading to the said burners, a stand-pipe, means for conducting gas into said stand-pipe, a series of gas-cocks connected with said stand-pipe, a gas-conveying pipe between each gas-cock and each gas-burner, an oscillating valve in each gas-cock provided with a forwardly-extending arm, and means arranged and constructed to successively engage the said arms, and actuate the oscillating valves of the gas-cocks, substantially as and for the purposes set forth.

6. In an apparatus for testing the volume of the air blown from the lungs of a person, the combination, with a casing, of a series of gas-burners, gas-conveying pipes leading to the said burners, a stand-pipe, means for conducting gas into said stand-pipe, a series of gas-cocks connected with said stand-pipe, a gas-conveying pipe between each gas-cock and each gas-burner, an oscillating valve in each gas-cock provided with a forwardly-extending arm, a bellows adapted to be expanded by forcing air into the same, and means for successively engaging the forwardly-extending arms and thereby actuating the valves of said gas-cocks, consisting of a bracket having ribs adapted to engage with the said arms for closing or opening the said valves, substantially as and for the purposes set forth.

7. In an apparatus for testing the volume of the air blown from the lungs of a person, the combination, with a casing, of a series of gas-burners, each burner comprising an inner gas-burning tube and an outer tube, gas-conveying pipes leading to the said inner gas-burning tubes, a series of gas-cocks, each cock being provided with an oscillating valve for admitting a full supply of gas to the inner gas-burning tube, means for closing the said gas-cocks, and an auxiliary gas-tube connected with said gas-conveying pipes and leading around each gas-cock for providing each burner with a constant but limited supply of gas, substantially as and for the purposes set forth.

8. In an apparatus for testing the volume of the air blown from the lungs of a person, the combination, with a casing, of a series of gas-burners, each burner comprising an inner gas-burning tube, gas-conveying pipes leading to the said inner gas-burning tubes, a series of gas-cocks, each cock being provided with an oscillating valve for admitting a full supply of gas to the inner gas-burning tube, means for closing the said gas-cocks, and an auxiliary gas-tube connected with said gas-conveying pipes and leading around each gas-cock for providing each burner with a constant but limited supply of gas, and a bellows adapted to be expanded by forcing air into the same, the said bellows being arranged to actuate the said closing means of said gas-cocks, and successively closing the valves of said cocks during the ascent of the bellows and opening said valves during the descent of the said bellows, substantially as and for the purposes set forth.

9. In an apparatus for testing the volume of the air blown from the lungs of a person, the combination, with a casing, of a series of gas-burners, each burner comprising an inner gas-burning tube and an outer tube, means for conducting gas into said stand-pipe, a series of gas-cocks connected with said stand-pipe, a gas-conveying pipe between each gas-cock and each inner gas-burning tube, an oscillating valve in each gas-cock for admitting a full supply of gas to the inner gas-burning tube, means for closing the said gas-cocks, and auxiliary gas-tubes connected with the said stand-pipe and the said gas-pipes which lead to the

aid inner gas-burning tube, the said auxiliary gas-tubes leading directly around the said gas-cocks, for providing each burner with a constant but limited supply of gas, substantially as and for the purposes set forth.

10. In an apparatus for testing the volume of the air blown from the lungs of a person, the combination, with a casing, of a series of gas-burners, each burner comprising an inner gas-burning tube, a stand-pipe, means for conducting gas into said stand-pipe, a series of gas-cocks connected with said stand-pipe, a gas-conveying pipe between each gas-cock and each inner gas-burning tube, an oscillating valve in each gas-cock for admitting a full supply of gas to the inner gas-burning tube, means for closing the said gas-cocks, and auxiliary gas-tubes connected with the said stand-pipe and the said gas-pipes which lead to the said inner gas-burning tubes, the said auxiliary gas-tubes leading directly around the said gas-cocks, for providing each burner with a constant but limited supply of gas, and a bellows adapted to be expanded by forcing air into the same, the said bellows being arranged to actuate the said closing means of said gas-cocks, and successively closing the valves of said cocks during the ascent of the bellows and opening the said valves during the descent of the said bellows, substantially as and for the purposes set forth.

11. In an apparatus for testing the volume of the air blown from the lungs of a person, the combination, with a casing, of a bellows adapted to be expanded, a series of gas-burners, and an intermediately-arranged mechanism between said bellows and the burners for successively releasing the gas-flames at the said burners, and then restoring said flames to their original size, substantially as and for the purposes set forth.

12. In an apparatus for testing the volume of the air blown from the lungs of a person, the combination, with a casing, of a bellows adapted to be expanded, a bracket on said bellows, provided with ribs, a series of gas-burners, and gas-cocks arranged in gas-conveying pipes connected with said bellows, and means on said gas-cocks with which said ribs on said bracket engage for closing and opening the said gas-cocks, substantially as and for the purposes set forth.

701,181. BED. ROBERT A. BARNETT, Riverside, Md. Filed Aug. 2, 1901. Serial No. 71,360. (No model.)

Claim.—1. A bed comprising a base-frame including side bars, series of spring supporting-arms extending upward from the side bars and having an interlocking connection therewith, eyes or loops formed intermediate the ends of said spring-arms, whereby the two ends of said spring-arms form guards stringer-rods extending through the eyes or loops on the spring-arms, a bed-bottom having attached side rods, and connections between the side rods and stringer-rods.

2. A bed comprising a base-frame including side bars, spring supporting-arms extending upward and inclining outward from the side bars and having an interlocking connection therewith, eyes or loops formed intermediate the ends of said spring-arms, whereby the two ends of said spring-arms form guards, stringer-rods extending through the eyes on the spring-arms and having terminal eyes which interlock with the eyes or loops of the spring-arms, a flexible bed-bottom, side rods connected therewith, and links interposed between said side rods and the stringer-rods.

3. A bed comprising a base-frame including side bars, series of spring supporting-arms extending upward and inclining outward therefrom and having an interlocking connection therewith, stringer-rods connected to the spring-arms, spring-arms extending above the stringer-rods and provided with terminal eyes, guard or finger rods inserted through said terminal eyes, a flexible bed-bottom, side rods connected therewith, and links connecting the side rods and stringer-rods at intervals.

4. A collapsible or knockdown bed embodying a base-frame consisting of side bars and cross-bars, spring-arms having an interlocking connection with the side bars and extending upward therefrom, stringer-rods connected with said spring-arms, a bed-bottom stretched and suspended between the stringer-rods, and arched canopy-supports located at opposite ends of the bed and having their extremities inserted in openings in the

base-frame, the canopy-supports also serving as means for preventing displacement of the cross-bars relatively to the side bars of the base-frame.

5. A collapsible or knockdown bed embodying a base-frame comprising side bars and cross-bars, spring supporting-arms having an interlocking connection with the side bars and bent to embrace said side bars, stringer-rods inserted through eyes or loops on the spring-arms, a flexible bed-bottom suspended between the stringer-rods, and arched canopy-supports having their extremities inserted into openings in the side bars, the cross-bars being confined between the canopy-supports and the portions of the spring-arms which embrace the side bars.

701,182. FIRE-HOOK. PAUL R. T. BERNER, Brooklyn, N. Y. Filed Apr. 18, 1901. Serial No. 68,388. (No model.)

Claim.—1. A fire-hook comprising spring-actuated pivoted members and an adjuster for the spring substantially as described.

2. A fire-hook comprising pivoted members, a spring for actuating the members, and a disk-shaped slide made to regulate the action of the spring and to act as a drag substantially as described.

3. A fire-hook comprising crusting members pivoted together, a spring for actuating the members, and a regulator adjustable on the spring for changing the action of the latter from opening to closing substantially as described.

701,188. VEL-FASTENER. WILLIAM BUSHNELL, New York, N. Y. Filed Mar. 28, 1900. Serial No. 68,464. (No model.)

Claim.—A vel-fastener, comprising an attaching-plate, adapted to be secured to a hat, a pin extending on the front face of the attaching-plate, and comprising a shank, having its base and extending at angles from the said plate and in an upward and outward direction, the base end of the shank terminating in an eye-curved portion, extending laterally and upwardly, and a point extending from the said curved portion and in the same direction, and reaching within a short distance of the base of the attaching-plate, as set forth.

701,184. PROCESS OF TREATING ORES. CHARLES J. BOW, Denver, Colo. Filed July 28, 1901. Serial No. 68,746. (No specification.)

Claim.—1. The process of treating ores, which consists in grinding them to a suitable fineness, supplying thereto a solution, consisting of a large proportion of water, a small proportion of acid and a salt mixture, consisting approximately of two parts common salt, one and one-quarter parts nitric acid, boiling the whole for a proper length of time, filtering the solution, precipitating the metallic portions by the application of sulfated hydrogen to the filtered solution, until a milky precipitate is formed, then heating each precipitate with the usual fluxes to drive off the vapors, then drawing off the metals, and then returning each solution and vapors for use in the heating-tank.

2. The process of treating ores, which consists in grinding them to a suitable fineness, supplying thereto a solution, consisting of a large proportion of water, a small proportion of acid and a salt mixture, consisting approximately of two parts common salt, one and one-quarter parts nitric acid, one and one-quarter parts alum and one and one-half parts nitric acid, boiling the whole for a proper length of time, filtering the solution, precipitating the metallic portions by the application of sulfated hydrogen to the filtered solution, until a milky precipitate is formed, then heating each precipitate with the usual fluxes to drive off the vapors, and then drawing off the metals.

3. The process of treating ores, which consists in grinding them to a suitable fineness, supplying thereto a solution, consisting of a large proportion of water, a small proportion of acid and a salt mixture, consisting approximately of two parts common salt, one and one-quarter parts nitric acid, one and one-quarter parts alum and one and one-half parts nitric acid, boiling the whole for a proper length of time, filtering the solution, precipitating the metallic portions by the ap-

precipitation of sulfureted hydrogen to the filtered solution, until a solid precipitate is formed, then heating such precipitate with the usual fluxes to drive off the vapors, and then drawing off the metals.

4. The process of treating ores, consisting of applying to the properly-ground ore a solution of from one to two parts acid, seventy to eighty parts water and titanium to twenty-five parts alkali mixture, consisting approximately of two parts common alkali, one and one-quarter parts nitric acid, one and one-quarter parts alum and one and one-half parts nitric acid, then boiling the compound for from one to two and a half hours, then drawing off the solution and causing a precipitation of the metallic portions to form a solid, then by the application of heat with the usual fluxes freeing the metals from the substances with which they are associated by reason of the preceding steps in the process.

5. The process of treating ores, consisting of applying to the properly-ground ore a solution of acid, water and a salt mixture, consisting approximately of two parts common alkali, one and one-quarter parts nitric acid, one and one-quarter parts alum and one and one-half parts nitric acid, then boiling the compound for from one to two and a half hours, then drawing off the solution and causing a precipitation of the metallic portions to form a solid, then by the application of heat with the usual fluxes freeing the metals from the substances with which they are associated by reason of the preceding steps in the process.

6. The process of treating ores, which consists in grading them to a suitable fineness, supplying thereto a solution consisting of water, acid and a salt mixture, consisting approximately of two parts common alkali, one and one-quarter parts nitric acid, one and one-quarter parts alum and one and one-half parts nitric acid, boiling the whole for a proper length of time, precipitating the dissolved metals as solids, then heating such precipitate with the usual fluxes to drive off the vapors, and then drawing off the metals.

701,185. SKYLIGHT-OPENER. GEORGE BOKERHART, New York, N. Y. Filed Jan. 24, 1908. Serial No. 91,970. (No model.)

Claim.—1. A skylight-opener, comprising a link pivotally connected at its upper end with a hinged skylight, a fixed bearing, a raising-bar slidable in the said bearing and pivotally connected at its lower end with the said link, a locking device on the fixed bearing for locking the bar to the bearing, and manually-controlled means for actuating the said locking device and imparting a sliding motion to the said bar, as set forth.

2. A skylight-opener, comprising a link pivotally connected at its upper end with a hinged skylight, a fixed bearing, a raising-bar slidable in the said bearing and pivotally connected at its lower end with the said link, a locking device on the fixed bearing for locking the bar to the bearing, and manually-controlled means for actuating the said locking device and imparting a sliding motion to the said bar; the said means comprising a pulley, a locking device, a pulley on the bearing, a pulley on the bar, and a pull-rope secured at one end to the raising-bar and extending over the said pulleys, as set forth.

3. A skylight-opener, comprising a link pivotally connected at its upper end with a hinged skylight, a fixed bearing, a raising-bar slidable

in the said bearing and pivotally connected at its lower end with the lower end of the said link, a spring-pressed lever-catch fulcrumed on the said fixed bearing and adapted to engage and lock the raising-bar in position, and means connected with the said catch and the said raising-bar to impart an initial movement to the said lever-catch to disengage the latter from the raising-bar, and to impart a sliding movement to the latter, as set forth.

4. A skylight-opener, comprising a link pivotally connected at one end with a hinged skylight, a fixed bearing, a raising-bar slidable in the said bearing and pivotally connected with the said link, a spring-pressed lever-catch fulcrumed on the said bearing and adapted to engage and lock the raising-bar in position, and means connected with the said catch and the said raising-bar to impart an initial movement to the said lever-catch to disengage the latter from the raising-bar, and to impart a sliding movement to the latter; the said means comprising a pulley journaled on the bearing, a pulley journaled on the bar, a pulley journaled on the lever-catch, and a pull-rope fixed at one end to the said bar and passing over the said pulleys, as set forth.

5. A skylight-opener, comprising a link pivotally connected at one end with a hinged skylight, a fixed bearing, a raising-bar slidable in the said bearing and pivotally connected with the said link, a locking device for locking the bar to the bearing, manually-controlled means for actuating the said locking device and imparting a sliding motion to the said bar, and a guide fixed on the said raising-bar for guiding the said link, as set forth.

6. A skylight-opener, comprising a link pivotally connected with a hinged skylight, a raising-bar having vertical guided movement and pivotally connected with the said link, a pivoted and spring-pressed lever-catch adapted to engage and lock the raising-bar, a pulley carried by the lever-catch, and pull-rope connected with the raising-bar and passing over the pulley on the lever-catch, as set forth for the purpose set forth.

701,186. DOOR-HOLDER. DAVID S. HAMPTON, Bostonville, Mass. Filed Oct. 31, 1901. Serial No. 90,007. (No model.)

Claim.—1. A door-holder comprising a normally straight resilient bar having a leg on each end, said legs being of substantially the same

length so that when the bar is depressed and spring under the door it will hold the door from being moved in either direction, substantially as described.

2. A door-holder comprising a resilient bar having legs thereon provided with feet, said feet having tapered toes constructed to engage and support said bar when depressed, substantially as described.

3. A door-holder comprising a normally straight resilient bar having a leg on each end, said legs being substantially of the same length, and rubber shoes on said legs to engage the floor and prevent slipping, each of said shoes comprising a piece of tubing secured by a clip having hooked ends engaging said feet, substantially as described.

701,187. INTERIOR-CONDUIT OUTLET-BOX. WILLIAM F. BARNETT, Utica, N. Y., assignor to the Barnett Electric Construction Company, Utica, N. Y. Filed Mar. 20, 1908. Serial No. 90,000. (No model.)

Claim.—1. An interior-conduit box, composed of an inner box portion to which the conduits are attached, provided with a cover having a central orifice; an outer box portion of less diameter than the orifice of the cover, and located therein, with a screw-threaded leg in the center of its bottom wall; with means for directly and positively supporting the said outer box portion from the bottom of the inner box portion, and means for adjusting the distance of one box portion to the other, and means also for adjusting the relative angle of one box portion to the other, as set forth.

2. An interior-conduit box, composed of an inner box portion provided with a cover having a central orifice; an outer box portion of less diameter than the orifice of the cover and located therein, having an outer rim and a screw-threaded leg in the center of its bottom wall, and other openings in said wall as described; with means for directly and positively supporting the said outer box portion from the bottom of the inner box portion, and means for adjusting the box portions toward one another and means also for adjusting the relative angle of the outer box portion to the inner portion, as set forth.

3. An interior-conduit box, composed of an inner box portion to which the conduits enter; a lamp-fixture support provided with a screw-threaded stud whose inner end has a supporting-surface adjustably held to a second surface in the bottom of the said inner box portion; a cover secured to said inner portion, having a central orifice; an outer box portion within the central orifice of the cover and adjustably supported upon the said threaded stud; with means at the bottom of said fixture-support for adjusting the said support and outer box portion at any angle.

4. An interior-conduit box, composed of an inner box portion to which the conduits are attached; a cover for the said box portion having a central orifice; an outer box portion adapted to enter the said cover-orifice freely, having a threaded leg in the center of its bottom; with means for adjustably supporting the said outer box portion to and from the said cover, and for tilting the same universally at any angle, consisting of an upright support whose outer end is screw-threaded and engaging the said threaded leg of the outer box portion, the support also adapted to contain a lamp-fixture, the inner end of the support provided with adjustable means for holding the same tilted from the bottom wall of the inner box portion.

5. An interior-conduit box, composed of an inner portion to which the conduits enter; a cover for the said inner portion, provided with a central orifice; an outer portion with substantially upright walls terminating in an outward rim, a screw nut or leg in the center of the bottom wall, which is also otherwise perforated as described; with a lamp-fixture support whose inner end has a supporting-surface adjustably held to a second surface in the bottom of the inner box portion and adapted to rotate thereupon, the outer end of said support consisting of a screw-threaded stud passing through and engaging with the said screw thread or leg, and a nut-nut upon the upper side of said leg.

6. An interior-conduit box, composed of an inner portion to which the conduits enter; a cover for the said inner portion, having a central orifice; and an outer portion provided with a screw-leg in the center of its bottom wall; with a lamp-fixture support having a screw-threaded stud projecting through and engaging said screw-leg, and whose inner end has a curved supporting-surface adjustably held to a second surface

in the bottom of the said inner portion, whereby the said outer portion may be raised and lowered upon the said stud, and be angularly adjusted relatively to the said inner box portion by the movement of the said curved surface upon the second surface, as set forth.

701,188. KNEE-BRAKE FOR STOPPING SPINNING-SPINDLES. JOHN ROTH, Bathwell, Scotland. Filed Feb. 1, 1908. Serial No. 90,142. (No model.)

Claim.—In spinning or doubling machines, the combination of the brake and spindle having a flanged whorve with a pivoted brake-lever, having a brake part projecting within the whorve-flange and adapted to act on the inner face thereof and at the other end of the lever a projecting part for the knee or limb of the operator to act on, substantially as described.

701,189. PUMP. ORVILLE J. BRACKLEY, Butler, Pa., assignor to himself and Thomas F. Ryan and Daniel A. Butler, Butler, Pa. Filed Jan. 6, 1908. Serial No. 90,612. (No model.)

Claim.—1. A pump comprising a tube, a ring arranged in the lower portion of the tube and forming a valve-seat, a valve supported on the

ring, an annular channel formed in the outer surface of the ring, the tube being provided with an opening in line with said channel and an opening having its axial line below the plane of the channel, and a spring-plate attached to the tube and having an inwardly-turned end for passing through the first-named opening and into the channel, substantially as specified.

2. A pump comprising a tube having an interior annular shoulder near its lower end, the said tube below said shoulder being tapered downward and outward, a valve-supporting ring correspondingly tapered at its outer side and adapted to engage its upper end against said shoulder, a valve supported on the ring, an annular channel formed in the outer surface of the ring, the tube being provided with an opening in line with said channel, and an opening having its axial line below the plane of the channel, a spring-plate attached to the tube and having an inwardly-turned end for passing through the first-named opening and into the channel, and a motor operating in the tube, substantially as specified.

3. In a pump, a tube, a valve-actuator secured to the lower end of said tube and having its outer surface flush with the tube, the said actuator being provided with an annular shoulder and tapered downward and outward from said shoulder, a valve-supporting ring tapered at its outer side to fit said taper of the actuator, the said ring having an annular channel, a valve on the upper end of the ring, the valve-actuator being provided with an opening in line with the channel of the ring and also with an opening on a lower plane than the channel, a spring-plate seated in a recess formed in the actuator and having an inwardly-turned portion for passing through the first-named opening and into said channel, the said actuator also having a depression or recess above the first-named opening, whereby an instrument may be inserted against the inner side of the plate, and a motor for operating in the tube, substantially as specified.

701,140. HYDROCARBON-OIL ENGINE. DWIGHT A. BROWN, Flint, Mich. Filed Feb. 4, 1908. Serial No. 82,821. (No model.)

Claim.—1. In a hydrocarbon-oil engine, a cylinder, a rib extended spirally around said cylinder and having openings through its coils, a jacket secured to said rib, an oil-supply pipe coiled around the cylinder between the coils of the rib, a vaporizing-chamber into which said coiled pipe discharges, a mixing-chamber communicating with said vaporizing-chamber and having communication with the interior of the cylinder, and a valve for controlling said communication, substantially as specified.

2. In hydrocarbon-oil engine, a cylinder, a rib extending spirally around said cylinder and having openings through its coils, a jacket secured to said rib, an oil-supply pipe coiled around the cylinder between the coils of the rib, a vaporizing-chamber, a spray-nozzle for receiving oil from the oil-pipe and discharging into said chamber, screens in said chamber below said nozzle, a cap surrounding the chamber and adapted to receive oil from the oil-pipe, a mixing-chamber at one side of the cylinder, a pipe leading from the vaporizing-chamber into said mixing-chamber, a valve for controlling the communication between said pipe and the mixing-chamber, a part in the wall of the cylinder communicating with said mixing-chamber, a valve for controlling said communication, and a screen in the opening which provides communication between said mixing-chamber and the port, substantially as specified.

3. In a hydrocarbon-oil engine, a cylinder, a rib extended spirally around the upper portion of said cylinder and provided with openings, an oil-supply pipe coiled around the cylinder between the coils of the rib, a supplemental heating-chamber on the cylinder and communicating with

said oil-pipe, a cap on the cylinder within said supplemental chamber, a vaporizing-chamber in said cap, an oil-pipe coiled around the vaporizing-chamber and communicating with the supplemental chamber, a nozzle leading from said pipe into the vaporizing-chamber, a mixing-chamber having communication with the interior of the cylinder, and a pipe leading from the vaporizing-chamber into said mixing-chamber, substantially as specified.

4. A hydrocarbon-oil engine comprising a cylinder, a rib extended spirally around the upper portion of the cylinder and having openings, an oil-supply pipe extended spirally around the cylinder, a jacket secured to the rib, a vaporizing-chamber on the cylinder and receiving oil from the oil-pipe, a casing on the cylinder having an opening for the inlet of air, a gas and air mixing chamber in a wall of the cylinder and having communication with the interior of the cylinder, means for controlling said communication, and a pipe leading from the vaporizing-chamber into said mixing-chamber, substantially as specified.

701,141. BELT. FRANK W. BROWN, CHASE, N. Y. Filed Feb. 4, 1901. Serial No. 74,608. (No model.)

Claim.—1. A belt having a transverse curvature which at the portion between the center and ends of the belt extends downwardly and outwardly from the upper edge of said belt, substantially as shown and described.

2. A belt having a transverse curvature terminating in straight ends, said curvature at the portions of the belt between the center and ends extending downwardly and outwardly from the upper edge of the belt, substantially as shown and described.

701,142. GARMENT-STRETCHER. EMORY A. BROWN, MAINE. Filed Nov. 20, 1901. Serial No. 81,728. (No model.)

Claim.—1. A transverse-stretcher, substantially as herein described, consisting of a roller tapered toward its middle and provided at each point with spurs, a cord attached to one end of said roller and having its free ends arranged to be tied around the material rolled in the roller, and the intermediate flexible sheet arranged to be wound with the legs of trousers around the roller, substantially as set forth.

2. A transverse-stretcher consisting of a roller and an intermediate flexible sheet arranged and adapted for use substantially as set forth.

3. A transverse-stretcher comprising a roller tapered toward its middle, an eye at one end of said roller, a string passed through said eye and secured with its ends free and adapted to be passed around the trousers when rolled, and the intermediate flexible sheet arranged and adapted for use, substantially as set forth.

701,143. TAPPING-MACHINE. JOHN W. BROWN, JR., PHILADELPHIA, Pa. Filed Apr. 20, 1908. Serial No. 14,978. (No model.)

Claim.—1. The combination of a standard, a spindle, a bracket, a tapered opening in the bracket, a tapered sleeve in the opening and having nuts at either end, a flange on the end of the spindle, a ring mounted on the flange, balls mounted between the ring and the nut on the end of the tapered bearing, a two-part casing secured to the bracket, a gear-wheel F mounted on the end of the spindle and having one or more legs, a gear-wheel G mounted on the lower section of the casing and also having one or more legs, a gear-wheel H meshing with the gear-wheel F, a gear-wheel J meshing with the gear-wheel H, and a gear-wheel K secured to the gear-wheel J and meshing with the gear-wheel G, a tapping-spindle passing through the gear-wheel G and into an opening in the end of the driving-spindle, a clutch-arm on the end of the tapping-spindle extending between the two gear-wheels F and G and arranged so as to be engaged by either the legs on the wheel F or the legs on the wheel G, substantially as described.

2. The combination in a tapping-machine of a frame having a bracket, a casing supported thereby, a driving-spindle extending into the casing and having a bearing in the bracket, a flange on the lower portion of the spindle and ball-bearings between said flange and the bracket, a gear-

wheel on the spindle provided with legs, a second gear-wheel in the casing below the first wheel and also having legs, intermediate gearing whereby the second gear-wheel may be driven from the first wheel, a tapping-spindle and a projection on said spindle constructed to be engaged by the legs of either gear-wheel, substantially as described.

3. The combination in a tapping-machine of a frame, a bracket projecting from said frame, a casing, a driving-shaft carried by the frame and extending into the casing, a sleeve carried by the bracket and surrounding said spindle, means for holding said sleeve stationary in the bracket, ball-bearings between the lower end of the spindle and said sleeve, a gear-wheel fixed to the lower end of the spindle having projecting legs, a second gear-wheel in the casing below the first wheel and also having legs, intermediate gearing whereby the second gear-wheel may be driven from the first wheel, a tapping-spindle and a projection on said spindle constructed to be engaged by the legs of either gear-wheel, substantially as described.

701,144. AXLE-NUT WRENCH. LAWRENCE E. BROWNE, BROOKLYN, N. Y. Filed Dec. 30, 1901. Serial No. 87,313. (No model.)

Claim.—1. In an axle-nut wrench, the combination of a spanner, resilient jaws secured to said spanner on opposite sides thereof, a rock-shaft journaled within said spanner and having a crank-lever secured thereto, and the hook-shaped arms secured to said shaft and having their free ends depending between said spanner and jaws and having a wedging contact therewith, substantially as set forth.

2. In an axle-nut wrench, the combination of the spanner, the resilient jaws secured to their rear ends to the head end of said spanner, the hook-shaped levers pivoted to said spanner and having their forward free ends underlaid between said spanner and jaws in wedging contact therewith, and means for operating said jaws in unison, substantially as set forth.

701,145. APPARATUS FOR MANUFACTURING CHARCOAL. CHARLES J. E. BROWN, SYRACUSE, N. Y. Filed May 20, 1901. Serial No. 81,638. (No model.)

Claim.—1. An apparatus for manufacturing charcoal comprising a combustion-chamber, a receiving-chamber for the wood to be charred, a plurality of heat-conducting passages communicating with the combustion-

chamber and arranged in proximity to different portions of the interior of the receiving-chamber, said passages being each provided with an insulating wall for preventing the escape of the products of combustion from the passages into the interior of the receiving-chamber, and means for controlling the flow of the products of combustion from the combustion-chamber through said passages independently and thereby rendering substantially uniform the treatment of the wood in the different portions of the interior of the receiving-chamber.

2. An apparatus for manufacturing charcoal comprising a combustion-chamber, a receiving-chamber for the wood to be charred, a plurality of heat-conducting passages communicating with the combustion-chamber and arranged in proximity to portions of the interior of the receiving-chamber substantially equidistant from each other, said passages communicating independently with the atmosphere and being each provided with an insulating wall for preventing the escape of the products of combustion from the passages into the interior of the receiving-chamber, and means for controlling the flow of the products of combustion from the combustion-chamber into the atmosphere through said passages independently and thereby rendering substantially uniform the treatment of the wood in the different portions of the interior of the receiving-chamber.

3. An apparatus for manufacturing charcoal comprising a combustion-chamber, a receiving-chamber for the wood to be charred, a main heat-conducting passage communicating with the combustion-chamber, a plurality of passages communicating independently with the main heat-conducting passage and also communicating independently with the atmosphere, said passages being each provided with an insulating wall for preventing the escape of the products of combustion from the passages into the interior of the receiving-chamber, and means for controlling the flow of the products of combustion from the combustion-chamber and the main heat-conducting passage to the atmosphere through said plurality of passages independently and thereby rendering substantially uniform the treatment of the wood in the different portions of the interior of the receiving-chamber.

4. An apparatus for manufacturing charcoal comprising a combustion-chamber, a receiving-chamber for the wood to be charred, said receiving-chamber being provided at its base with heat-conducting passages communicating with the combustion-chamber and arranged in proximity to different portions of the interior of the receiving-chamber and being provided with additional passages which communicate with the former passages and extend within the interior of the receiving-chamber and outwardly through the wall thereof, said former and additional passages being each provided with an insulating wall for preventing the escape of the products of combustion from the passages into the interior of the receiving-chamber, and means for controlling the flow of the products of combustion from the combustion-chamber and the former passages through said additional passages independently and thereby rendering substantially uniform the treatment of the wood in the different portions of the interior of the receiving-chamber.

5. An apparatus for manufacturing charcoal comprising a combustion-

chamber, a receiving-chamber for the wood to be charred, said receiving-chamber being provided at its base with a main heat-conducting passage communicating with the combustion-chamber, and a plurality of passages communicating with the main heat-conducting passage and leading therefrom in proximity to different portions of the interior of the receiving-chamber, and being provided with a plurality of additional passages which communicate with the former passages and extend within the interior of the receiving-chamber and outwardly through the wall thereof, said former and additional passages being each provided with an insulating wall for preventing the escape of the products of combustion from the passages into the interior of the receiving-chamber, and means for controlling the flow of the products of combustion from the combustion-chamber and the former passages through said additional passages independently and thereby rendering substantially uniform the treatment of the wood in the different portions of the interior of the receiving-chamber.

6. An apparatus for manufacturing charcoal comprising a receiving-chamber for the wood provided with a main heat-conducting passage, substantially horizontal heat-conducting passages formed in the base of the receiving-chamber and communicating with the main heat-conducting passage and extending outwardly therefrom, and additional heat-conducting passages communicating with the outer ends of the substantially horizontal heat-conducting passages and extending upwardly therefrom, said additional heat-conducting passages having their upper ends projected outwardly through the side walls of the receiving-chamber and provided with exits and closures therefor, and means for conducting the gases and vapors from the receiving-chamber, substantially as and for the purpose set forth.

7. An apparatus for manufacturing charcoal comprising a receiving-chamber for the wood provided with a main heat-conducting passage, substantially horizontal heat-conducting passages formed in the base of the receiving-chamber and communicating with the main heat-conducting passage and extending outwardly therefrom, a substantially ring-shaped heat-conducting passage communicating with the outer ends of the former passages, and additional heat-conducting passages extending upwardly therefrom, said additional heat-conducting passages having their upper ends projected outwardly through the side walls of the receiving-chamber and provided with exits and closures therefor, and means for conducting the gases and vapors from the receiving-chamber, substantially as and for the purpose described.

8. An apparatus for manufacturing charcoal comprising a combustion-chamber, a receiving-chamber for the wood to be charred, a plurality of heat-conducting passages communicating with the combustion-chamber and arranged in proximity to different portions of the interior of the receiving-chamber, said passages being each provided with an insulating wall for preventing the escape of the products of combustion from the passages into the interior of the receiving-chamber, means for controlling the flow of the products of combustion from the combustion-chamber through said passages independently and thereby rendering substantially uniform the treatment of the wood in the different portions of the interior of the receiving-chamber, a conduit for conducting the gases and vapors from the receiving-chamber, means for cooling the gases and vapors, and a conduit for conducting the cooled gases from said means to the receiving-chamber and cooling the charcoal, substantially as described.

9. An apparatus for manufacturing charcoal comprising a combustion-chamber, a receiving-chamber for the wood to be charred, a plurality of heat-conducting passages communicating with the combustion-chamber and arranged in proximity to different portions of the interior of the receiving-chamber, said passages being each provided with an insulating wall for preventing the escape of the products of combustion from the passages into the interior of the receiving-chamber, means for controlling the flow of the products of combustion from the combustion-chamber through said passages independently and thereby rendering substantially uniform the treatment of the wood in the different portions of the interior of the receiving-chamber, a conduit for conducting the gases and vapors from the receiving-chamber, means for cooling the gases and vapors, and a conduit for conducting the cooled gases from said means to the combustion-chamber, substantially as described.

10. An apparatus for manufacturing charcoal comprising a receiving-chamber for the wood provided with heat-conducting passages at its base, a combustion-chamber communicating with the heat-conducting passages, a conduit for conducting the gases and vapors from the receiving-chamber, a condenser having a substantially upright passage for ascending fluid provided with an inlet at its base and an outlet at its top, and substantially upright passages communicating at their upper ends with the condenser, a second conduit, means for conducting the condensed vapors and gases from the lower ends of the upright passages thence to the second conduit, and a gas-conduit communicating with said means and the combustion-chamber, and provided with a chamber containing a wire-gauze partition, substantially as and for the purpose described.

11. An apparatus for manufacturing charcoal comprising a combustion-chamber, a receiving-chamber for the wood to be charred having a plurality of openings extending through its side walls and closures for said openings, a plurality of heat-conducting passages communicating with the combustion-chamber and arranged in proximity to different portions of the interior of the receiving-chamber, said passages being each provided with an insulating wall for preventing the escape of the products of combustion from the passages into the interior of the receiving-chamber, and means for controlling the flow of the products of combustion from the combustion-chamber through said passages independently and thereby rendering substantially uniform the treatment of the wood in the different portions of the interior of the receiving-chamber.

701,146. BAG HANDLE OR CARRIER. EDWARD L. GARDNER and WILLIAM H. GARDNER, Detroit, Mich. Filed Mar. 17, 1902. Serial No. 98,592. (No model.)

Claim.—In a bag-carrier, a conical loop bent laterally near its ends, handles on said ends, and a conical loop having eyes at its ends to engage the laterally-projecting ends of the other loop.

701,147. DRESS-SUPPORTER. MARTHA J. GARDNER, Sherman, Tex. Filed Feb. 4, 1902. Serial No. 98,593. (No model.)

Claim.—A dress-supporter comprising a longitudinally-bowed plate to fit the body at a point adjacent the base of the spine, a spring applied completely against the rear convex side of the plate and converged toward its opposite terminus, suspending device having their lower terminals attached to the plate whereby the latter may be loosely hung from the shoulders of the wearer, and a reinforce-hanger having its lower end attached to the plate at a point intermediate of the attachment thereof of the suspending device, said hanger being also secured to the said suspending device.

701,148. FLUID-CUTTER. JAMES GARDNER, Detroit, Mich. Filed July 18, 1901. Serial No. 94,896. (No model.)

Claim.—1. In a fluid-cutter, the combination with a spindle having a cam formed thereon, of a tool-guard loosely mounted upon the spindle and provided with openings in its sides, cutters carried by the guard and adapted to be projected radially through said openings by the cam, and means on the spindle to engage the guard to hold the cutters projected during the cutting operation.

2. A fluid-cutter comprising a spindle having a cam formed thereon, a tool-guard mounted on the spindle, cutters carried by said guard and adapted to be moved radially by the cam when the spindle is rotated, a

cutting-pin carried by the spindle to engage the guard, whereby the spindle and guard are rotated together and the cutters are held projected during the cutting operation, substantially as specified.

3. A fluid-cutter comprising a spindle having annular grooves formed thereon, a tool-guard carrying cutters mounted on the spindle, a cam formed on the spindle to engage the cutter and project them radially when the spindle is partially rotated, a pin carried by the spindle to engage the guard and arrest the independent movement of the spindle, a gage revolved on the spindle, and means to prevent the spindle from wobbling, substantially as specified.

4. In a fluid-cutter, the combination with a spindle, having an eccentric formed thereon, of a tool-guard mounted upon the spindle, and provided with diametrically-arranged openings, radially-movable cutters mounted in said openings, and adapted to contact with the eccentric formed on the spindle, a cutting-pin carried by the spindle, laps formed on the ends of the tool-guard with which the cutting-pin contacts to revolve the guard, the sleeve 5, collar 6 for clamping the spindle, and a gage revolved upon the spindle, substantially as shown and described.

701,149. PHOTOGRAPH-HANGER. GEORGE H. GRANT, Portland, Ore. Filed Apr. 26, 1901. Serial No. 97,974. (No model.)

Claim.—A picture-hanging instrument having a vertical shaft, a pair of jaws attached thereto, and extending horizontally therefrom, one of said jaws being rigidly attached to the shaft, and the other of said jaws consisting of a horizontal bar pivoted near one end to the first jaw, and a gripping portion attached to the horizontal portion at or near the middle, means for attaching a pull-cord at the opposite end of said horizontal bar, and a spring for holding the pivoted jaw pressed toward the stationary jaw, substantially as specified.

701,150. BUILDING-BLOCK. JAMES W. GREENWOOD, Cleveland, Ohio. Filed Feb. 4, 1902. Serial No. 98,548. (No model.)

Claim.—1. As a new article of manufacture, a building-block comprising two slabs of concrete or similar material rigidly secured together by means of a metallic framework comprising two or more sets of cross-braces connected by rods embedded in the material of the respective slabs, said slabs having their adjacent faces parallel and separated from each other, substantially as described.

2. As a new article of manufacture, a building-block comprising two slabs of concrete arranged with their adjacent faces parallel and separated from each other, means for securing said slabs together, comprising a series of braces having their ends embedded in the material of the respective slabs and extending from the upper portion of one slab to the lower portion of the other slab, and a similar series of braces extending from the upper portion of the last-mentioned slab to the lower portion of the first-mentioned slab; means for securing the respective braces together at the points where they cross each other; and means embedded in the material of said slabs for locking the ends of the said braces in the said slabs, substantially as described for the purpose set forth.

3. As a new article of manufacture, a building-block comprising two slabs of concrete or similar material, one slab embedded in the upper and one in the lower portion of each slab, and a series of cross-braces secured together at their outer points and having their ends secured to the said rods in the respective slabs, the said cross-braces being arranged so that their outer points will fit without the material constituting the said slabs, substantially as described and for the purpose set forth.

4. As a new article of manufacture, a building-block comprising two slabs of concrete or similar material arranged with their adjacent faces separated from each other, a series of braces arranged with their ends embedded in the material of the respective slabs, and extending from the upper portion of one slab to the lower portion of the other slab, a similar series of braces extending from the upper portion of the last-mentioned slab to the lower portion of the first-mentioned slab, and means embedded in the material of the said slabs for locking the ends of the said braces in the respective slabs, substantially as described and for the purpose set forth.

701,151. MUFFLER. CHARLES E. CHRISTMAN, San Jose, Cal., assignor to Christman Motor Carriage Co., San Jose, Cal., a Corporation of West Virginia. Filed Jan. 20, 1902. Serial No. 99,466. (No model.)

Claim.—1. A muffler comprising an outer cylinder and an inner cylinder, means for connecting the exhaust with the inner cylinder, and a plurality of condensing-pipes and a plurality of discharge-pipes, the former communicating with the interior of the inner cylinder and the latter communicating with the atmosphere, and both sets of pipes located in the space between the inner and the outer cylinders, substantially as and for the purpose set forth.

2. A muffler comprising an outer cylinder and an inner cylinder, said inner cylinder provided with means for connecting with the exhaust-pipe, a plurality of condensing-pipes and a plurality of discharge-pipes located within the space between the two cylinders, the condensing-pipes communicating at one end with the interior of the inner cylinder and at their opposite ends communicating with the space between the two cylinders, and the discharge-pipes communicating at their opposite ends with the space between the two cylinders and with the atmosphere respectively, whereby the steam, vapor or gas is discharged into the same, substantially as and for the purpose specified.

701,152. TELEPHONE SYSTEM. HENRY F. CLARK, Chicago, Ill., assignor to American Electric Telephone Company, a Corporation of New Jersey. Filed Apr. 26, 1901. Serial No. 97,999. (No model.)

Claim.—1. In a telephone system, the combination with subscribers' lines, of a central office at which the lines terminate, operators' connective means at the central office to variously connect said lines together for conversational purposes, supervisory signals associated with said means to indicate the condition of the telephones at the connected subscribers' stations, and a circuit-breaking device adapted to open the circuit to one station when the supervisory signal assigned to the other is operated.

2. In a telephone system, the combination with subscribers' lines, of a central office at which the lines terminate, operators' connective means at the central office to variously connect said lines together for conversational purposes, subscribers' stations having telephones and hooks, and circuit-breaking device adapted to open the circuit to one of two connected subscribers when the telephone of one subscriber is off the hook and the telephone of the other subscriber is upon the hook.

3. In a telephone system, the combination with subscribers' lines, of a central office at which the lines terminate, operators' connective means at the central office to variously connect said lines together for conversational purposes, subscribers' stations being provided with telephones and hooks, and a relay and circuit connections adapted to open the circuit to a connected subscriber when his telephone is off the hook and the other subscriber's telephone is upon the hook.

4. In a telephone system, the combination with subscribers' stations having receivers and hook-switches, metallic telephone-lines extending

therefrom in a central office, operators' connective circuits to connect said lines together for conversational purposes, and a relay adapted and arranged to open one side of the circuit of a connected subscriber when one subscriber's receiver is off the hook and the other subscriber's receiver is open the hook.

5. In a telephone system, the combination with subscribers' stations having receivers and hook-switches, metallic telephone-lines extending therefrom to a central office, operators' connective circuits to connect said lines together in pairs for conversational purposes, supervisory signals associated with said means to indicate the condition of the subscribers' instruments when connected together, and a circuit-breaking device adapted and arranged to open the circuit to one connected subscriber when the supervisory signal assigned to the other is operated.

6. In a telephone system, the combination with subscribers' stations having receivers and hook-switches, metallic telephone-lines extending therefrom to a central office, operators' connective circuits to connect said lines together in pairs for conversational purposes, supervisory signals associated with said means to indicate the condition of the subscribers' instruments when connected together, said signals being operated over one side of the metallic circuits and ground, and a relay adapted and arranged to open the other side of the circuit to one subscriber when the supervisory signal for the other subscriber is operated.

7. In a telephone system, the combination with metallic telephone-lines, subscribers' stations having hook-switches connected to one line conductor and normally grounded, cord-circuits at the central office to interconnect said lines for conversational purposes, relays connected across the line, a common battery connected between said coils and ground, supervisory signals controlled by said relays, and relays arranged for automatically opening the metallic circuit of one connected line when the signal of the other is operated.

8. In a telephone system, the combination with metallic telephone-lines, subscribers' stations having hook-switches connected to one line conductor and normally grounded, cord-circuits at the central office to interconnect said lines for conversational purposes, relays connected across the line, a common battery connected between said coils and ground, supervisory signals controlled by said relays, and circuit-breaking devices controlled by said relays for opening the circuit to one station when the signal assigned to the other is operated.

9. In a telephone system, the combination with metallic telephone-lines, hook-switches at the subscribers' stations connected to one line conductor and normally grounded, cord-circuits at the central office to interconnect said lines for conversational purposes having their strands connected with tip and sleeve contacts of the plugs, circuit-closing relays bridged across the cord-circuits, a common battery connected between a point intermediate said relays and earth, supervisory signals controlled by said relays and associated respectively with the ends of the cord-circuit, and circuit-breaking relays also controlled by said circuit-closing relays to open either end of the cord-circuit when the signal associated with the other end is operated.

10. In a telephone system, the combination with metallic lines, hook-switches at the subscribers' stations connected to one line conductor in the same unvarying relation and normally grounded, cord-circuits to interconnect said lines for conversational purposes having their strands connected with tip and sleeve contacts of the plugs, relays bridged across the cord-circuits, a common battery connected between a point intermediate said relays and earth, said relays being operated over the grounded line conductors and corresponding strands of the cord-circuit, supervisory signals associated with the ends of the cord-circuit, and relays for opening the other strands of the cord-circuit, said latter relays being operated when one subscriber's receiver is open the hook and the other subscriber's receiver is off the hook.

11. In a telephone system, the combination with metallic lines, hook-switches at the subscribers' stations connected to one line conductor in the same unvarying relation and normally grounded, a cord-circuit to interconnect said lines for conversational purposes, circuit-closing relays connected across the cord-circuit, a common battery connected between a point intermediate said relays and earth, supervisory signals controlled by said relays assigned to each end of the cord-circuit, circuit-breaking relays to open each end of the cord-circuit also controlled by said circuit-closing relays, and local circuits each including said battery and one of said circuit-breaking relays, the circuit-breaking relays at one end of the cord-circuit operating when the supervisory signal at the opposite end is operated.

12. In a telephone system, the combination with metallic telephone-lines, hook-switches at the subscribers' stations connected in unvarying relation with one line conductor, signal-bells grounded by said hook-switches, a central office at which the lines terminate, individual signals at said office for said lines, a common battery to which said lines and signals are normally connected, an operator's cord-circuit comprising plugs and strands between the tip of one plug and sleeve of the other, two circuit-closing relays in a bridge of the cord-circuit, the middle point of which bridge is connected with said battery, said relays being adapted to be operated over the grounded line conductors and corresponding strands of the cord-circuit when a connection is established, supervisory signals associated with said plugs and controlled by said relays, and circuit-breaking relays to open the cord-circuit on one side of the bridge when a circuit-closing relay is operated over the other strand on the other side.

13. In a telephone system, the combination with metallic telephone-lines, hook-switches at the subscribers' stations connected in unvarying relation with one line conductor, signal-bells grounded by said hook-switches, a central office at which the lines terminate, individual signals at said office for said lines, a common battery to which said lines and signals are normally connected, an operator's cord-circuit comprising plugs and strands between the tip of one plug and sleeve of the other, two circuit-closing relays in a bridge of the cord-circuit, the middle point of which bridge is connected with said battery, said relays being adapted to be operated over the grounded line conductors and corresponding strands of the cord-circuit when a connection is established, supervisory signals associated with said plugs and controlled by said relays, and circuit-breaking relays arranged to open the cord-circuit and operated by either of the circuit-closing relays, whereby when a signal associated with one plug is operated the circuit-breaking relays are also operated to open the cord-circuit.

14. In a telephone system, the combination with metallic telephone-lines, hook-switches at the subscribers' stations connected in unvarying relation with one line conductor, signal-bells grounded by said hook-switches, a central office at which the lines terminate, individual signals at said office for said lines, a common battery to which said lines and signals are normally connected, an operator's cord-circuit comprising plugs and strands between the tip of one plug and sleeve of the other, two circuit-closing relays in a bridge of the cord-circuit, the middle point of which bridge is connected with said battery, said relays being adapted to be operated over the grounded line conductors and corresponding strands of the cord-circuit when a connection is established, supervisory signals associated with said plugs and controlled by said relays, circuit-breaking relays arranged to open the cord-circuit and operated by either of the circuit-closing relays, and a grounded ringing generator at the central office to operate the subscribers' bells.

701,158. **ENTRANCE-JOURNAL**, THOMAS GALT, Youngstown, Ohio. Filed Dec. 28, 1901. Serial No. 67,000. (No model.)

Claim.—1. In a signal device of the class described, a trumpet-shaped sound-flare having its outer bell disposed exterior to a building, means for holding and operating an alarm within the flare, and a protective bonnet or shield arranged over and spaced from the exterior bell, said bonnet or shield being of sufficient area to completely cover the bell.

2. In a signal device of the class described, the combination of a sound-trumpet arranged to receive an explosive alarm, and having an en-

terior bell, a protective bonnet or shield arranged over and spaced from the exterior bell of the trumpet, and an auxiliary alarm housed beneath and within the plane of the protective bonnet or shield and comprising means, disposed within the plane of the trumpet, actuated by the explosion from the explosive alarm.

3. In a device of the class described, a sound-trumpet arranged to receive an explosive alarm and having its bell exposed exterior to a building, a protective bonnet or shield supported over and spaced from the bell of the trumpet, an auxiliary continuous alarm, an impact-plate movably supported in the interval between the trumpet-bell and the protective bonnet or shield, said impact-plate having guiding means and provided with a ruffled portion, and tripping devices actuated by the impact-plate and cooperating with said auxiliary alarm.

4. In a device of the class described, a sound-trumpet arranged to receive an explosive alarm, a protective bonnet arranged over and spaced from the bell of the trumpet, means arranged within the bonnet and having a plurality of guides, an auxiliary alarm mounted within the bonnet, an impact-plate movably supported in the interval between the trumpet-bell and the bonnet and provided with members engaging said guides, and an operating-stem connected with the impact-plate and having a tripping connection with the auxiliary alarm.

701,154. **WRENCH-FRAME**, ARTHUR COLL, New Haven, Conn. Filed Mar. 12, 1902. Serial No. 66,978. (No model.)

Claim.—1. A combined necktie frame and holder, constructed of a single piece of spring-wire bent upon itself, forming spaced upwardly and rearwardly curved wing-sections, a central bottom-clamping section between the wings, including front and rear members, and an open loop connecting the upper ends of the rear members, and a substantially V-shaped bottom section extending from the lower inner portions of the wings to a point below the bottom-clamping section at the vertical center of the frame, substantially as described.

2. A combined necktie frame and holder, constructed of a single piece of wire bent upon itself to form spaced upwardly and rearwardly curved wing-sections, the upper members of the wing-sections being curved and the lower members curved, the said wire being further bent to form a central bottom-clamping section at the inner ends of the upper members of the wings, which bottom-clamping section includes front and rear members below the upper members of the wings, the rear members having an inclination at their upper ends in direction of the forward members, and an open loop connecting the upper ends of the rear members of the bottom-clamping section, which open loop is substantially at its bottom portion and is flaring at its upper or mouth portion, the wire being still further bent upon itself to form a V-shaped central lower section extending some distance below the central clamping-section, the ends of the wire being secured together at the point of the said central lower section, as and for the purpose described.

701,155. **STOP-MOTION FOR MECHANICAL TOYS**, ARTHUR D. CRAWFORD, Winchester, Mass. Filed Mar. 24, 1901. Serial No. 66,980. (No model.)

Claim.—1. A vehicle provided with a motor for imparting motion

to a body of the wheels, and a check for the wheels, brought into and out of action by raising the wheels of the vehicle from or bringing said wheels into engagement with a supporting-surface.

2. In mechanical toys, a motor-controlled driving-axle having movement to and from the body of the vehicle to which it is applied, and a check for the motor, operated by the movement of the axle, as set forth.

3. In mechanical toys, a driving-axle for a vehicle, a motor for the driving-axle, a projection from the axle and a stop arranged for engagement with the projection, the projection and stop being automatically brought into engagement when the vehicle is placed upon a surface upon which it is adapted to travel, said stop and projection being immediately carried out of engagement when the vehicle is raised from said surface, the engagement of the stop and projection serving to prevent an expenditure of power on the part of the motor.

4. A driving-axle for a vehicle, a motor having driving connection with said axle, the motor having movement to and from the vehicle-body, a stop carried by the fixed support, and a projection from the driving-axle, arranged for engagement with the said stop and for disengagement from the stop through the weight of the vehicle with which the axle is connected.

5. A driving axle for a toy vehicle, a fixed support for the axle, in which fixed support the said axle has sliding movement, a stop carried by one of the said supports, a projection from the axle, adapted to engage with the stop when the axle is in one position, the said stop being out of engagement with the projection from the axle when said axle is in its other position, and a motor connected with said axle, as described.

6. In toy vehicles, the combination, with the body of the vehicle, axle for the same, the driving-axle having movement in its pedestal to and from the body, of a motor connected with the driving-axle and having pivotal connection with the body of the vehicle, a projection from the driving-axle, and a stop-peg adapted for engagement with the said projection, which stop-peg is attached to a fixed support, the projection from the driving-axle being in the path of the stop-peg only when the said axle is in its lower position.

7. In a toy vehicle, the combination, with a vehicle-body and a motor supported thereby, of an axle operatively connected with said motor, whereby said axle is rotated and the vehicle propelled, said axle being capable of a rising-and-falling motion relatively to the said body, a ratchet carried by said axle, and an arm arranged to engage said ratchet as the axle falls, and check its rotation, substantially as described.

8. The combination, with a vehicle-body having a motor, an axle rotated by said motor, a ratchet on said axle, a locking-arm for engaging said ratchet, means for moving said axle away from said body and carrying said ratchet into engagement with said locking-arm, substantially as described.

9. The combination, with a vehicle-body, of a rotating axle, means for moving said axle relatively to said body, and means for locking said axle from rotating when it is moved away from said body, substantially as described.

10. The combination of a vehicle-body having dotted legs, an axle held in said dotted legs, whereby said axle is capable of moving toward or away from said body, wheels attached to said axle, one of said wheels having ratchet-shaped teeth, an arm arranged to engage said teeth when the axle is moved away from said body, and means for rotating said axle against said arm, substantially as described.

11. In a toy vehicle, the combination with a body and an axle carried by said body and capable of a falling motion as the body is raised, of a motor applied to propel the vehicle, and means controlled by said falling axle to check the movement of the vehicle, substantially as described.

701,156. **APPARATUS FOR CLOSING OR OPENING WATER-DOORS**, WILLIAM CRAWFORD and ARTHUR D. CRAWFORD, Winchester, Mass. Filed Aug. 26, 1901. Serial No. 67,001. (No model.)

Claim.—1. Apparatus for automatically closing bulkhead-doors for

ships comprising a liquid-pressure accumulator, a cylinder secured upon the movable door, piping connecting said accumulator and said cylinder, a shaft geared to a rack or racks on said door, the said shaft being normally held stationary by a clutch, and means for releasing said clutch operated by a diaphragm automatically actuated by the rise of water in the ship's bilges.

2. Apparatus for automatically opening and closing bulkhead-doors for ships, comprising a liquid-pressure accumulator, a cylinder secured upon the movable door, piping connecting said accumulator and said cylinder, a piston within said cylinder, a shaft geared to a rack or racks on said door, a clutch-shaft normally clutched to the geared shaft, capable of rotation in one direction to open the door, but held by a pawl and ratchet to prevent rotation in the opposite direction, and means, operated by a diaphragm automatically actuated by the rise of water in the ship's bilges, for releasing said clutch to permit of the door being closed by the fluid-pressure.

3. Apparatus for closing and opening water-tight bulkhead-doors, comprising in combination a cylinder secured upon the movable door, a hollow piston and piston-rod, upon which said cylinder works, secured to the bulkhead or framing of the doorway, a pipe connection to the end of said hollow piston-rod from an accumulator, a shaft having bearings in brackets on the door-framing and having spur-wheels fitted upon it, racks on the movable door in gear with said spur-wheels, a second shaft in line with the spur-wheel shaft, a sliding clutch on the second shaft normally engaging the spur-wheel shaft, a device for withdrawing said clutch to allow the door to be closed by the fluid-pressure, a hand-lever for operating the clutch-shaft to open the door, and a ratchet and pawl for preventing the closing of the door until the withdrawal of the clutch by the releasing device, substantially as described.

4. In apparatus for closing and opening water-tight bulkhead-doors, means for normally retaining the door in open position, said means consisting, in combination with a bulkhead-door having racks upon it and a shaft fitted with spur-wheels in gear with said racks, of a shaft in line with the spur-wheel shaft, and having a clutch adapted to engage normally with the spur-wheel shaft, a ratchet-wheel actuated by the clutch-shaft, and a pawl engaging said ratchet to prevent the shafts from turning by the fluid pressure on the door, substantially as described.

5. In apparatus for closing and opening bulkhead-doors, the means for automatically closing the door consisting, in combination with a bulkhead-door having racks upon it, and a shaft fitted with spur-wheels in gear with said racks, of a cylinder secured upon said door, a hollow piston and piston-rod working in said cylinder, the end of the rod being connected in the bulkhead or framing of the doorway, a pipe connection from said hollow piston-rod to an air-pressure vessel containing air or other fluid, and a diaphragm operated by the rising of water in the ship's bilges to free a clutch from the spur-wheel shaft, substantially as described.

701,157. SPEED-REGULATING CLUTCH. HENRY E. GREENE. New Canaan, Conn. assignor of one-half to W. F. Schneider. Filed June 27, 1901. Serial No. 60,989. (No model.)

Claim.—In a speed-regulating clutch, the combination of a shaft to be driven, a wheel loosely mounted on said shaft, a collar at one side of said wheel, a clutch-collar engaging the other side of said wheel, clutch-arms pivoted to said clutch-collar, friction-shoes pivoted to said clutch-arms and projected on the interior of the wheel where they are adapted to engage the inner surface of said wheel, and a coil-spring controlling said clutch-arms and effecting an engagement of the friction-shoes with the inner surface of the wheel at such times when the tension of said spring is not overcome by the centrifugal force due to the movement of the shaft, substantially as specified.

701,158. BREAKDOWN GUN. WILLIAM H. DAVENPORT. Norwich, Conn. Filed Aug. 7, 1901. Serial No. 71,173. (No model.)

Claim.—1. In combination, is a breakdown gun, a frame and barrel hinged together substantially as set forth, a leg beneath the barrel and extended forward of the hinge-joint, and a strap secured to the said leg extension.

2. In combination, is a breakdown gun, a frame and barrel hinged together substantially as set forth, a barrel-leg extended forward of the hinge-joint, a strap secured to said leg extension, a fore-wood abutting the said fore-wood strap and means for securing the fore-wood to the barrel.

701,159. LOCKING-KEY FOR FIREARM. WILLIAM H. DAVENPORT. Norwich, Conn. Filed Aug. 7, 1901. Serial No. 71,174. (No model.)

Claim.—1. In combination, is a screw-key, a threaded pin, an operating-head having a stem that is longitudinally movable in said pin; and means for preventing the rotation of said stem relatively to the said threaded pin the opposite end of said stem being extended through the pin, substantially as specified.

2. In combination with the frame and barrel of an arm, a key for locking said parts together consisting of a threaded pin adapted to be screwed into said frame, an operating-stem that is longitudinally movable in said pin and means for preventing the rotation of the stem in the said pin.

3. In combination, a barrel, a frame having a recess of, a key for locking together said frame and barrel, consisting of a threaded pin screwed into said frame, and operating-head having a stem that is longitudinally movable in said pin; and means for holding the said stem against rotation relatively to the said threaded pin the said operating-head being adapted to enter the said frame-recess, substantially as and for the purposes specified.

4. In combination with the frame and barrel of an arm, a locking-key consisting of a threaded pin that is adapted to be screwed into the said frame, one end of said pin being capped, as set forth, a stem mounted to slide longitudinally in said pin; and means for holding the said stem against rotation in the threaded pin one end of said stem being formed with an enlarged operating-head and the opposite end being extended to enter the capped end of the pin.

701,160. RAIL-JOINT. EDWARD F. DAVENPORT. New Canaan, Conn. Filed Jan. 18, 1902. Serial No. 60,990. (No model.)

Claim.—1. A railroad-joint comprising rail-sections one of which has the terminal portion of the web increased in thickness and projected to form an extension with upper and lower grooves therein, the contiguous rail-section terminal having the web longitudinally slotted at an intermediate point and adapted to be embraced by the extension of the web of the other rail-section, and a single fastening-bolt passing vertically through one rail-section and a portion of the extended web of the other section.

2. A rail-joint comprising rail-sections, one section having the web extended and embracing the web of the other section, and a single bolt passing vertically through one section and a portion of the extended web of the other section.

3. A rail-joint comprising rail-sections continuously arranged, one section having the web extended and embracing a portion of the web of the opposite section, the extended web being vertically slotted, and a single fastening-bolt passing through one section and the slot in the extended web of the other section, the said slot being greater in diameter than the bolt.

4. A rail-joint comprising continuously-arranged rail-sections, a portion of one rail-section embracing a part of the other and having a vertical slot therethrough and upper and lower grooves, and the embraced portion of the other section longitudinally slotted at an intermediate point, and a single fastening-bolt passing vertically through the section having the longitudinal slot and the extended portion of the other section.

701,161. DEVICE FOR WARNING BRIDLE-BITS. GEORGE DAVIS. Lyons, N. Y. Filed Feb. 2, 1902. Serial No. 60,441. (No model.)

Claim.—The combination with a lantern, of a cap bearing an indentation designed to engage a bridle-bit and support it, there being an aperture in the bottom of said indentation, and a slide closing said aperture and constructed to be withdrawn to expose said bit to the direct heat of the flame, substantially as described.

701,162. FRICTION-GEAR. EDWARD F. DAVENPORT. New Canaan, Conn. assignor of one-third to Howard W. Pierce. Filed Jan. 17, 1902. Serial No. 60,100. (No model.)

Claim.—1. The combination of two rotary frictional members arranged with their axes out of alignment, a transmitting-wheel bearing between said members, a slide on which the wheel is mounted, a frame carrying the slide, and means for moving the slide, said means comprising a spring actuating the slide in one direction and a cord to draw the slide against the action of the spring.

2. The combination of two rotary cones having their axes out of alignment and having their opposite faces extending parallel to each other, a transmitting-wheel having its axis extending across the axes of the cones and movable between the said parallel faces of the cones, a slide carrying the transmitting-wheel, and a frame in which the slide is movable, the frame extending between said opposite faces of the cones and essentially parallel therewith.

3. The combination of two rotary cones having their axes out of alignment and having their opposite faces extending parallel to each other, a transmitting-wheel having its axis extending across the axes of the cones and movable between the said parallel faces of the cones, means for mounting the transmitting-wheel, the said means for mounting the transmitting-wheel comprising a slide carrying the wheel and a frame in which the slide is movable, a spring drawing the slide in one direction, and a flexible connection attached to the slide for moving it against the action of the spring.

4. The combination of two rotary cones having their axes out of alignment and having their opposite faces extending parallel to each other, a frame running between and essentially parallel with said opposite faces, a slide carried on the frame, a transmitting-wheel mounted on the slide, said wheel having its axis extending across the axes of the cones, and means for shifting the slide on the frame.

5. The combination of two rotary frictional members arranged with their axes out of alignment and having their opposite faces parallel to each other, a frame extending in parallelism with said opposite faces, a slide mounted on the frame, a transmitting-wheel carried by the slide and engaging the said opposite faces of the frictional members, a spring drawing the slide in one direction, and a flexible connection attached to the slide to permit moving it against the action of the spring.

701,163. COMBINED AIR AND WATER PUMP. EDWARD D. DAVENPORT. New Canaan, Conn. Filed Feb. 22, 1901. Serial No. 60,400. (No model.)

Claim.—1. In a pneumatic system for water elevation, a sealed tank, a water-carrier leading therefrom, a pump comprising a cylinder having an outlet connected with the tank, a water-pumping device consisting of a plunger-rod, and a head thereon having means for the upward passage of water and air, an air-induction device coacting with the water-pumping device and having a valve for controlling the amount of air pumped, and adjustable devices for controlling the movement of said valve.

2. In a pneumatic system for water elevation, a sealed tank, a water-carrier leading therefrom, a pump combining water lifting and forcing mechanism, and an air-induction device adapted to control the introduction of air below the plunger-head during a part of the upward stroke of the plunger-rod, the said device comprising a valve controlling an air-passage leading below the plunger-head, means for opening said valve at a predetermined point in the upward movement of said plunger-rod, and an outlet for the water and air leading from the cylinder above the plunger-head and connected with the tank.

3. A pump, comprising a cylinder, a hollow plunger-rod, a plunger-head on the rod having a valve-controlled water-passage and an air-passage, a valve-stem in the hollow plunger-rod, a valve on the valve-stem and controlling the said air-passage in the plunger-head, and means for opening said valve at a predetermined point in an upward movement of the plunger-rod.

4. A pump, comprising a cylinder, a water-supply pipe thereon, a hollow plunger-rod, a plunger-head on said rod through which water passes after it enters the cylinder, a valve-stem movable in the hollow plunger-rod, a valve on said stem and controlling an air-passage through the plunger-head, means for opening said valve during the upward movement of the plunger-rod, and means for holding it in the open position.

5. A pump, comprising a cylinder, a water-supply pipe connected therewith, a hollow plunger-rod, a plunger-head on said rod through which water passes after it enters the cylinder, a valve-stem movable in the hollow plunger-rod, a valve on said stem and controlling an air-passage through the plunger-head, the said valve being normally closed, a device for adjusting said valve to the open position during the upward movement of the plunger-rod, and means for releasing said valve to allow it to return to closed position.

6. A pump comprising a cylinder, a depending water-supply pipe thereon, a check-valve controlling the opening of the supply-pipe into the cylinder, a hollow plunger-rod, a head thereon slidably engaging the bore of the cylinder and having a water-passage therethrough, a vertically-reciprocating disk valve controlling said water-passage, an outlet-pipe on the cylinder above the plunger-head, and an air induction and controlling device adapted to pass air down through the plunger-head during each upward movement of the plunger-head, the said device comprising a valve controlling a passage through the plunger-head, a valve-stem extending upward from said valve, means for moving said valve-stem, to open the valve at a predetermined point in the upward movement of the plunger-rod, means for holding said valve in the open position, and means for releasing said valve.

7. A pump, comprising a cylinder, a depending water-supply pipe thereon, an outlet-pipe connected with the cylinder, a hollow plunger-rod, a threaded socket screwing on the lower end of the plunger-rod, a cylindrical valve-chamber screwing into a projection of said socket, and a plunger-head consisting of a perforate base-plate, a headed clamping-bolt screwing in the lower end of the cylindrical chamber to hold the base-plate in position, the said clamping-bolt having a central passage formed therein, a cupped flexible packing resting on the base-plate, a disk cap-plate seated within the packing-ring and engaged by the threaded socket to press the cap-plate upon said packing-ring, a disk valve slidably held be-

tween the cap-plate and the base-plate and which normally seats over the perforations in the base-plate, a valve-stem arranged to reciprocate in the hollow plunger-rod and a valve on said stem and adapted to be seated over the passage in the clamping-bolt.

8. An air and water pump, comprising a cylinder, a water-supply pipe depending therefrom, an outlet-pipe laterally extended from the cylinder near its upper end, a hollow plunger-rod, a cylindrical valve-chamber secured on the lower end of said hollow rod, a plunger-head having a water-passage therethrough, a disk valve slidable on the valve-chamber and controlling the passage through the plunger-head, a headed bolt having a passage therethrough and holding the plunger-head on the valve-chamber and plunger-rod, a valve-stem reciprocating in the hollow plunger-rod, a valve on the lower end of the valve-stem and seating over the passage in the headed bolt, and means held on the cylinder and adapted to control adjustment of said valve to hold it open or permit its closure.

9. An air and water pump, comprising a cylinder, a water-supply pipe thereon, an outlet-pipe, a hollow plunger-rod, an apertured plunger-head, a disk valve adapted to control the passage in the plunger-head, a headed bolt holding the plunger-head on the rod and having a longitudinal passage therethrough, a valve-stem in the plunger-rod, a valve thereon seating over the passage in the headed bolt, a rockably-supported tappet-lever held loosely engaged at one end with the valve-stem, the other end thereof being free, an upright post at one side of the cylinder, having a lateral arm at the upper end, an adjustable spring-link depending from one side of the post and adapted to rock the free end of the tappet-lever downwardly, spring-coils embracing the free end of the tappet-lever so as to hold it rocked, and a pressure-block depending from the arm on the post, and adapted to spread apart the spring-coils for the release of the tappet-lever when said lever and arm are fully elevated by the upward movement of the hollow plunger-rod.

10. In a pneumatic system for water elevation, a sealed tank, a water-service leading therefrom, a pump-cylinder, a hollow plunger-rod, a plunger-head on said rod and provided with openings through which water passes after it enters the cylinder, an air-induction device comprising a valve-stem movable in the hollow plunger-rod, a valve carried thereby and controlling the passage of air below the plunger-head and adjustable device controlling the movement of said valve-stem to regulate the opening-and-closing movement of said valve.

11. A pump, comprising a cylinder, a hollow plunger-rod, a plunger-head on the rod having a valve-controlled water-passage and an air-passage communicating with the interior of the hollow plunger-rod, a valve-stem movable in the hollow plunger-rod, a valve on the valve-stem and controlling the air-passage in the plunger-head, and means for controlling the movement of said valve-stem to hold the valve open or permit its closure.

701,164. SHADE-ROLLER BRACKET. James J. De Lona, Brooklyn, N. Y. Filed Jan. 2, 1901. Serial No. 41,908. (No model.)

Claim.—1. A shade-roller bracket in which is comprised a base-plate having a slide-way therein formed by turning over the edges of the material, and a single perforation, and a slot for the passage of a holding screw or nail, in combination with a movable bracket-piece for the reception of a shade-roller bearing arranged to engage in the slide-way, the said bracket-piece having an opening for the reception of a retaining screw or nail which registers with the slot in the base-plate.

2. A shade-roller bracket in which is comprised a base-plate having a slide-way therein formed by turning over the edges of the material, and a single perforation, and a slot for the passage of a holding screw or nail, in combination with a movable reversible bracket-piece for the reception of a shade-roller bearing arranged to engage in the slide-way, the said bracket-piece having an opening for the reception of a retaining screw or nail which registers with the slot in the base-plate.

3. A shade-roller bracket in which is comprised a base or holding plate having a slide-way therein formed by turning over the edges of the material, and a single perforation for the passage of a holding nail or screw, in combination with a bracket-piece arranged to engage in the slide-way, said bracket-piece being provided with an opening for the reception of a holding nail or screw, which also passes through the base or holding plate.

701,165. BUILDING-BLOCK. ALFRED H. MAX, New York, N. Y. Filed Sept. 2, 1901. Serial No. 74,128. (No model.)

Claim.—1. A floor construction, comprising floor-supporting beams, and floor-blocks arranged one alongside the other and extending between and supported from the adjacent floor-supporting beams, the said blocks being arranged to form dead-air spaces between the floor-supporting beams and the ends of adjacent blocks, the blocks having interlocking top and bottom flanges, as set forth.

2. A floor construction, comprising floor-supporting beams, and floor-blocks arranged one alongside the other and extending between and supported from the adjacent floor-supporting beams, the said blocks being arranged to form dead-air spaces between the floor-supporting beams and the ends of adjacent blocks, the said blocks being interlocked and fastened together at the interlocking joints by a suitable binding substance, and the blocks forming dead-air spaces between adjacent blocks, as set forth.

3. A floor-block of substantially an I-beam cross-section, and having transverse partitions near its ends to reach close to the edges of the flanges of the floor-supporting beams, and longitudinal lips extending outwardly from the partitions to reach to the webs of adjacent floor-supporting beams, as set forth.

4. A floor-block, of substantially an I-beam cross-section and having its top flange extending beyond the ends of the web, and lips projecting from the ends of the web, as set forth.

5. A floor-block, of substantially an I-beam cross-section and having its top flange extending beyond the ends of the web, and lips projecting from the ends of the web under the said top flange, as set forth.

6. A floor-block, of substantially an I-beam cross-section and having its top flange extending beyond the ends of the web, and lips projecting from the ends of the web and a distance beyond the same, as set forth.

7. A floor-block, of substantially an I-beam cross-section and having its top flange extending beyond the ends of the web, and the bottom flange terminating at the ends of the web, and lips projecting from the ends of the web in line therewith and beyond the ends of the said top flange, as set forth.

8. A floor-block, of substantially an I-beam cross-section, and having transverse partitions at the ends of the web, the top flange extending beyond the partitions, as set forth.

9. A floor-block, of substantially an I-beam cross-section, and having transverse partitions at the ends of the web, the top flange extending beyond the partitions, the bottom flange terminating at the partitions and having its ends beveled, as set forth.

10. A floor-block, of substantially an I-beam cross-section and having transverse partitions at the ends of the web, the top flange extending beyond the partitions, and lips projecting outward from the partitions in line with the web, and strengthening members at the top and bottom flanges of the block and extending longitudinally thereof, as set forth.

11. A floor-block, of substantially an I-beam cross-section and having transverse partitions at the ends of the web, the top flange extending beyond the partitions, lips projecting outward from the partitions in line with the web, and strengthening members at the top and bottom flanges of the block and extending longitudinally thereof, as set forth.

12. A floor-block of substantially an I-beam cross-section, and having recesses in its top and supporting-eyes having twisted channels embedded in the web of the block, the eyes extending in the said recesses, as set forth.

13. A floor-block, of substantially an I-beam cross-section and having transverse partitions at the ends of the web, the edges of the partitions and those of the top and bottom flanges being arranged to interlock with the corresponding edges of adjacent blocks, as set forth.

14. A floor-block of substantially an I-beam cross-section and having lips at the ends thereof above the bottom flange of the block, and a tension member extending in the bottom flange and the said lips, as set forth.

15. A floor-block of substantially an I-beam cross-section, and having lips at the ends thereof above the bottom flange of the block, and a tension member extending in the bottom flange and the said lips at the middle of the flange and lips, as set forth.

16. A floor-block of substantially an I-beam cross-section and having lips at the ends thereof, and a tension member longitudinally embedded in the block at the bottom thereof and extending into the lips thereof, the ends of the tension member terminating a distance from the ends of the lips, as set forth.

17. A floor-block of substantially an I-beam cross-section and having lips at the ends thereof, and a tension member longitudinally embedded in the block at the bottom thereof and extending into the lips thereof, and reinforcing-wires longitudinally embedded in the block near the edges of the flanges of the block, as set forth.

701,166. APPARATUS FOR THE RECEPTION OF SOUND-SIGNALS FOR NAUTICAL PURPOSES. Edouard De Rougemont, Brussels, Belgium. Filed Sept. 22, 1901. Serial No. 75,928. (No model.)

Claim.—1. An apparatus for the reception of sound-signals characterized by the combination of a tubular ring, a tube provided with an earpiece fitted to said tubular ring, a series of ear-trumpets arranged to receive the sound waves, a series of tubes connecting the ear-trumpets with the tubular ring and means for closing and opening the said tubes.

2. An apparatus for the reception of sound-signals characterized by the combination of a tubular ring, a tube provided with an earpiece fitted to said tubular ring, a series of ear-trumpets arranged to receive the sound waves, a series of tubes connecting the ear-trumpets with the tubular ring, the orifices of said tubes being arranged around the ring in order corresponding with the position of the ear-trumpets, plugs or interceptors fitted to the said tubes, means for opening and closing the said plugs or interceptors and a handle for introducing a tube through which a sound enters the tubular ring.

3. In apparatus for the reception of sound-signals the combination with a tubular ring, a tube provided with an earpiece fitted to said tubular ring, a series of sound-conducting trumpets and a series of tubes connecting the ear-trumpets with the tubular ring, of interceptors fitted to the said tubes, toothed wheels mounted on the axis of said interceptors and whose rotation produces the opening and closing of the said interceptors, a rotatable disk provided upon a part of its circumference with teeth which can gear with the said toothed wheels for turning them, and a handle mounted upon the axis which carries the said disk in such manner that when it is made to turn around the said axis it turns the disk and the disk.

4. In apparatus for the reception of sound-signals in combination, a tubular ring provided with an internal partition, a tube provided with an earpiece fitted to the said tubular ring, a series of sound-conducting trumpets, tubes connecting the said trumpets with the said tubular ring and means for closing successively one or more of the said tubes at a time.

701,167. VISE. Jean Bismar, Lowell, Mass. Filed Aug. 11, 1901. Serial No. 24,024. (No model.)

Claim.—1. A vise comprising a movable jaw, a check connected therewith and provided with two sets of ratchet members, a toggle-arm provided with means to engage one set of ratchet members to move said jaw, and retaining means for engaging the other set of ratchet members to hold said jaw, the toggle being arranged to operate independently of the retaining means.

2. A vise comprising a movable jaw provided with a check having a set of ratchet-teeth, two companion pawls having complementary teeth arranged to engage said ratchet, the teeth of one pawl being arranged in advance of the other, as described, and means for moving said check arranged to disengage said pawls, or to move said check without engaging said pawls.

701,167.

701,168. CENTER-IRON AND LAP-RING. PERKINS H. DU ROSS, New York, N. Y. Filed Feb. 2, 1902. Serial No. 92,995. (No model.)

Claim.—1. A device of the class set forth, comprising a cuff with a forwardly-projecting head having independent openings therein, and a lap-link comprising two members having portions individually engaging the said openings and movable vertically to open and close the cuff.

2. The combination with a center-iron having a head with a pair of openings therein, the said openings being flared toward the front, and a lap-link comprising a pair of members having flanges movably passing through the said openings, the said members being spread apart and drawn together in a vertical plane in the opening and closing movements thereof.

3. In a center-iron and lap-link, the combination with a center-iron having a head formed with a pair of openings, and an inner groove, and a lap-link comprising a pair of members having flanges movably extending through the said openings to permit the members to be opened and closed in a vertical plane, the inner flange of the flange being in the form of transverse bands movably engaging the groove.

701,169. CALENDAR-BLISTER. STANLEY M. DOWDY, Rochester, N. Y. Filed Sept. 2, 1901. Serial No. 74,186. (No model.)

Claim.—1. A blister, comprising a frame, and clamping device mounted on said frame, and each having two members which are provided with two separate gripping-surfaces adapted to respectively engage the under face of a blotting-sheet on the bottom of said frame, and the upper face of superimposed sheets on the top of said frame.

2. A calendar-blister, comprising a frame having a segmental bottom, a blotting-sheet on said bottom, a calendar on the top of said frame, and a clamping device yieldably supported on the frame and provided with two members which are formed with gripping-surfaces adapted to respectively engage the under face of the blotting-sheet and the top face of the calendar.

3. A calendar-blister, comprising a frame having a segmental bottom, a blotting-sheet on said bottom, a calendar on the top of said frame, and clamping device individually fitted to the ends of the frame, each clamping device having members disposed at an angle to each other and formed with gripping-surfaces arranged to hold the blotting-sheet and the calendar separately and removably in place on the frame.

4. A calendar-blister, comprising a frame having a segmental bottom, a blotting-sheet on said frame, a calendar on the top of said frame, and spring clamping-clips at the ends of the frame and each provided with separate gripping-surfaces disposed at an angle to each other, said gripping-surfaces of each clip adapted to individually hold the end portions of the blotting-sheet and the calendar portions of the calendar.

5. A calendar-blister, comprising a frame having a segmental bottom, a blotting-sheet on said frame, a calendar on the top of said frame, clips at the ends of the frame and provided with angularly-disposed members which have gripping-surfaces adapted to individually hold the blotting-sheet and said calendar in position on the frame, and springs pressing said clips and holding both members thereof in active engagement with the blister and the calendar.

6. The combination with a frame, of clips held on the ends of said frame, each clip having angularly-disposed members which are provided with gripping-surfaces arranged in opposing relation to the under side and the top face of the frame respectively, a clamping-plate at the top of the frame, and springs pressing the clips for both surfaces thereof to occupy active relation to the frame.

701,170. AWNING. SAMUEL DUNN, Boston, U. S. A. Filed Jan. 18, 1902. Serial No. 92,973. (No model.)

Claim.—1. In an awning, the combination of a winding-spindle having a gear on one extremity thereof mounted adjacent to said gear and having a vertically-disposed sleeve terminating in a lower yoke carrying a pinion which is held in constant mesh with said gear, an overlying engaging the winding-spindle, supporting means for the screw at the extremity opposite that engaging the winding-spindle, a winding-rod freely movable through said sleeve and pinion, and means for rotating the said winding-rod.

2. In an awning, the combination with an awning proper and a winding-spindle, of a winding-rod for rotating said spindle and operative mechanism for said winding-rod comprising a horizontally-disposed gear connected to the rod by a universal joint, and a primary rotating-pinion adjustable in relation to the gear and connected to the lower extremity of the rod.

701,171. GAME. JAMES R. DUNN, New York, N. Y. Filed Mar. 14, 1902. Serial No. 92,996. (No model.)

Claim.—1. A set of men for a game, comprising pieces each having a direction-mark at a corner, a piece having a direction-mark at a corner, and parallel lines at each side of the direction-mark, a piece having a direction-mark at a corner, parallel lines at each side of the direction-mark, and a line crossing the parallel lines at each end thereof, and a piece having a direction-mark at a corner, parallel lines at each side of the direction-mark, and a line crossing the parallel lines at each end thereof.

2. A set of men for a game comprising pieces each having a direction-mark at a corner and a row of dots in line therewith, a piece having a direction-mark at a corner, parallel lines on each side of the direction-mark, and rows of dots in line with the latter, a piece having a direction-mark at a corner, parallel lines on each side of the direction-mark, and rows of dots in line with the direction-mark, and a piece having a direction-mark at a corner, parallel lines on each side of the direction-mark, parallel lines crossing the parallel lines at each end thereof and rows of dots in line with the direction-mark.

701,172. BUCKLE-FASTENER. ALBERT H. BOW, Boston, U. S. A. Filed May 4, 1901. Serial No. 92,792. (No model.)

Claim.—1. A buckle-fastener, comprising a steel member having a head, and a clip member comprising a plate having an opening through which the head may pass, the said plate being provided at its center with oppositely-arranged depressions extending from the opening to the edges of the plate, whereby the sides of the plate are permitted to spring or move relatively to each other, substantially as specified.

2. In a buckle-fastener, a steel comprising a base-plate, a clasp member projecting from the base-plate, a head of oval contour on the other end of the clasp, and a collar or flange arranged at the base of the head, and a plate-like clip member apertured to receive the head and provided with a longitudinal depression at each side of the opening and extending to the edge of the plate, substantially as specified.

3. A buckle-fastener, comprising a steel member having a head, and a clip member comprising a plate having an opening to pass over the head, the said plate having oppositely-arranged depressions extending from the opening to the edges of the plate, the sides of said plate being carried outward and then inward toward each other to engage over the outer end of the head, substantially as specified.

4. In a fastening device, the combination with a headed steel, of a plate having an opening through which the head of the steel may pass, and oppositely-arranged depressions on said plate, said depressions extending in a direction across the opening, from the opening to the edge of the plate, substantially as specified.

701,173. SAFETY DEVICE FOR BLASTING PURPOSES. JAMES H. DOWDY, New York, N. Y. Filed June 4, 1901. Serial No. 92,141. (No model.)

Claim.—1. In a safety device for blasting purposes, the combination with a fuse and a cap attached to one extremity thereof, of a tubular open-ended sheath through which the fuse is passed, the cap being located beyond the inner extremity of the sheath, said sheath being of a size to fit the fuse quite closely, but at the same time to permit the easy insertion and removal of the cap and fuse, the arrangement being such that the tamping material is pushed around and exterior to the sheath.

2. The combination with a fuse, and a cap applied to one extremity of the fuse, of a tubular open-ended sheath through which the fuse is passed, the cap being located beyond the inner extremity of the sheath which is of sufficient rigidity to maintain its form against the external pressure of the tamping material which is placed around and exterior to the sheath.

3. In a safety device for blasting purposes, the combination with a fuse and a cap attached to one extremity thereof, of a tubular open-ended sheath through which the fuse is passed, the cap being located beyond the inner extremity of the sheath, substantially as described.

4. The combination with a cap and fuse, of a wire fastened to the cap end of the fuse, the fastening or knot in the wire being inside the cap when the latter is applied to the fuse end, the said wire being carried along the fuse endwise and suitably connected therewith, and a tubular sheath through which the fuse and wire may be passed, and permitting the removal of the wire and the cap, after the hole has been filled and tamped.

5. The combination with a cartridge, fuse and cap, the cartridge having an opening to receive the cap end of the fuse, and a tubular sheath for the fuse, said sheath being connected with the cartridge-end, and extending the entire length of the hole in the rock, whereby the fuse is protected and its removal together with the cap, made practicable.

6. The combination with a fuse and a cap applied to one end thereof, of an open-ended tube through which the fuse is passed, the cap being located beyond the inner extremity of the tube which is composed of sections and constructed and arranged to protect the fuse and permit its withdrawal after the hole is filled.

701,174. APPARATUS FOR TESTING THE MAGNETIC QUALITIES OF MATERIALS. CHARLES V. BENTLEY, New York, N. Y. Filed Feb. 24, 1902. Serial No. 92,997. (No model.)

Claim.—1. An apparatus for testing the magnetic qualities of materials comprising a plug, a bobbin attached thereto having a central bore to receive a core formed in the material to be tested, a magnetizing-coil

carried by said bobbin, device for making and breaking the circuit of said coil, another coil carried by said bobbin, and indicating device included in the circuit of said coil.

2. An apparatus for testing the magnetic qualities of materials comprising a plug having a tapered end and a central bore adapted to fit a hole formed in the material to be tested, and to receive a core of the material within said hole, a bobbin attached to the plug, a magnetizing-coil carried by said bobbin, another coil carried by the bobbin, and indicating device included in the circuit of said last-mentioned coil.

3. An apparatus for testing the magnetic qualities of materials comprising a magnetizing-coil adapted to encircle a core formed on the material to be tested, a coil arranged concentrically with the magnetizing-coil, indicating device in the circuit of said last-mentioned coil, and a compensating device connected with said coils for the purpose specified.

701,175. PAPER-STOP. HAROLD F. BOWEN, Turner Falls, Mass. Filed Sept. 26, 1901. Serial No. 73,094. (No model.)

Claim.—1. In connection with a winding-drum, a stop mounted on the drum and adapted to swing transversely of the drum while winding the material thereon.

2. In connection with a winding-drum, a stop-arm adjustable longitudinally and axially of the drum.

3. A paper-stop in connection with a winding-drum, consisting of a carriage adjustable longitudinally on the drum, and an arm mounted to swing on said carriage axially of the drum.

4. A paper-stop for a winding-drum, comprising a rack on the drum, a carriage movable on the rack, a spring-pressed dog on the carriage and engaging with the rack, and a stop-arm mounted to swing on the carriage.

5. A paper-holding device on a winding-drum, comprising a rack attached to the drum, a carriage movable on said rack, a spring-pressed dog mounted on the carriage and engaging with the rack, a lifting device for the dog, and a stop-arm mounted to swing on the carriage.

6. In connection with a winding-drum, a carriage movable longitudinally of the drum, an arm mounted to swing on said carriage, and means for locking the arm on the carriage.

7. In connection with a winding-drum, a carriage adjustable longitudinally of the drum, a stop-arm having spring-yielding pivotal connection with the carriage, and a locking connection between the carriage and arm.

8. In connection with a winding-drum, a carriage adjustable longitudinally of the drum, and a curved stop-arm mounted to swing on said carriage.

9. In connection with a winding-drum, a rack secured in a channel in the drum, a carriage comprising an upright plate and side plates, a spring-pressed dog mounted in the carriage and engaging with the rack, a shaft having bearings in the side plates, a cam on said shaft for engaging with the dog, a stop-arm, a pivot-pin on said stop-arm and extending through the upright plate of the carriage, a spring yielding connection between said pin and the carriage, and a spring-pressed pin mounted in the carriage and adapted to engage in an opening in the said arm.

701,176. CAN-GAPPER. JOHN R. DUNN, Indianapolis, Ind., assignor of one-half to the Specialty Manufacturing Company, Indianapolis, Ind. Filed Aug. 19, 1901. Serial No. 72,619. (No model.)

Claim.—1. A machine for sealing cans by pressing the lid thereof into the mouth or opening in the can including a support for the can, a pressure-head for engaging, containing the lid and pressing it down into a sealing position, and means for actuating said pressure-head.

2. A machine for sealing cans by pressing the lid thereof into the mouth or opening in the can including a support for the can, a pressure-head for engaging, containing the lid and pressing it down into a sealing position, a rod carrying said pressure-head, a guide for guiding said rod and pressure-head, and means for actuating the pressure-head.

3. A pressure-head for sealing cans having a central extension to enter the depression in the can-lid and an annular flat surface about said extension to engage the rim of the lid or pressing it into place.

4. A pressure-head for sealing cans having an annular pressing-surface for engaging the rim of the lid and pressing them into the can, and a central extension beveled on its outside surface and adapted to enter the depression in the lid and abutment against the bottom of the lid in the final movement of the pressure-head.

5. A sealing-block for cans while the cans are being sealed having a series of concentric circular depressions of varying diameters and elevations within and between said depressions that are substantially flush with the top surface of the block and with each other.

6. A sealing-block for cans while being sealed having a series of concentric circular depressions of varying diameters to receive the bottoms of the cans, said depressions increasing in depth from the center of the block outward.

701,177. CIL-SURFER. BRADLEY W. DUNE, San Jose, Cal. Filed Mar. 26, 1901. Serial No. 62,911. (No model.)

Claim.—1. In an apparatus for boring petroleum, the combination of a table having openings made through the surface, with flanges sur-

rounding said openings and projecting above the table surface, open-topped fuel-supply pipes extending above said surface, and heads therefor closed at the top and open at the bottom.

2. In an apparatus for boring petroleum, the combination of a burning-table having openings made through with raised flanges surrounding said openings, fuel-supply pipes extending upwardly through and above the surface of the table, closed top heads fitting over said pipes, and extending downwardly to near the surface of the table, said heads having discharge-openings at the bottom and through the sides.

3. In an apparatus for boring petroleum, the combination of a burner-plate having openings, with raised flanges surrounding said openings, open-topped fuel-supply pipes extending above the table surface, and having annular projecting and downwardly-divergent flanges around the upper end, closed top heads of larger diameter than said flanges, said heads having discharge-openings at the bottom and through the sides.

4. In an apparatus for boring petroleum, the combination of a chamber, means for introducing a fluid fuel therein, a burner-plate located above said chamber having holes made therethrough, with raised flanges surrounding said openings, open-topped fuel-supply pipes extending through said chamber and above the burner-plate, annular flanges surrounding the tops of the pipes divergent downwardly, closed top heads of larger diameter than the flanges, fitting over the pipes above the burner-plate having discharge-openings at the bottom and through the sides.

5. In an apparatus for boring petroleum, the combination of a burner-plate having openings with flanges surrounding the same and projecting above the upper surface of said burner, open-topped fuel-supply pipes extending above said plate and heads encompassing the upper ends of said pipes, a closed chamber below the burner-plate, and a pipe within said chamber for supplying gaseous fuel thereto said pipe having passages leading from it to a point above the plate.

6. In an apparatus for boring petroleum, the combination of an upper-passed chamber, an intermediate burner-plate, liquid-fuel-supply pipes extending upwardly through said plate, and distributor connected therewith, and gaseous-fuel-supply pipes disposed within the lower chamber having perforations and passages made in them, said burner-plate having openings through which said gaseous fuel passes.

701,178. NAIL-MAKING MACHINE. HENRIQUE DUBOIS, Montreal, Canada. Filed Apr. 16, 1901. Serial No. 65,894. (No model.)

Claim.—1. In a nail-making machine of the class described, a nail-forming mechanism limited to two sets of dies, one of said sets of dies having its members formed to point the nails by a compression action solely on the wire, and the other set of dies having head-forming die-cores in their casting dies and in the dies which oppose the point-compressing dies, combined with means for intermittently and positively reciprocating the set of head-forming dies, while they are gripped upon

the wire, in a direction contrary to the feeding of the wire and less compressive relation in the set of nail-pointing dies, to upset the wire at intervals and form the nail-heads substantially as described.

2. In a nail-making machine of the class described, a nail-forming mechanism limited to two sets of dies, one of which comprises a stationary relation to the other and said relatively stationary dies formed and driven to point and shape the nails by a compression action solely on the wire, and the other set of dies provided with head-forming die-cores in the cooperative faces thereof and in the faces which oppose the point-compressing dies, combined with means for opening and closing each set of dies intermittently, and means for positively feeding said head-forming dies gripped upon a wire, toward and in cooperative relation to the relatively stationary shaping-dies, whereby two sets of dies operate on a wire to head and point the nails, as set forth.

3. In a nail-making machine, the combination of a set of relatively stationary shaping and pointing dies, another set of independent head-forming dies having gripping-dies and head-forming die-cores, die-actuating means whereby the dies of each set may be forcibly gripped upon the stock, and quickly opened prior to advancement of the stock, and means for positively moving the set of head-forming dies toward the shaping and pointing dies and for lifting said head-forming dies on the return movement thereof, whereby the head-forming dies are given ample clearance for the nail-heads, substantially as described.

4. In a nail-machine, the combination of a set of casting dies provided with means for opening and closing the same, another set of dies having their active faces beveled to point the nails or heads by a compression action and also provided with means for opening and closing said dies, an intermittent feed mechanism effective to advance a wire in one direction when both sets of dies are opened, and means for positively moving one set of dies toward the other set of dies at a period when both sets of dies are closed and gripped upon the wire, such movement of the dies being in a direction contrary to that of the wire under the action of the feed mechanism, substantially as described.

5. In a nail-machine, a relatively stationary die-block, a lever fulcrumed on the die-block and provided with a roller-shoe, casting dies mounted in the die-block and the lever respectively and provided with grooves in their opposing faces, and a cam arranged to ride against the head of said lever and thereby positively move the latter to open and close said dies, in combination with a feed mechanism, a set of casting head-forming dies, and means for positively moving said head-forming dies in a direction contrary to the line of feed of the work, substantially as described.

6. In a nail-machine, the combination with casting shaping-dies, and a dotted lever for opening and closing said dies, of a head-forming lever passing through the dotted lever and provided with a roller-shoe, a cam arranged to ride against said shoe, a spring connected with the head-forming lever for holding the same in a retracted position, an adjustable stop in the path of the head-forming lever, and cooperating work-engaging devices movable with the casting head-forming dies, substantially as described.

7. In a nail-making machine of the class described, the combination with nail-pointing mechanism, and a suitable feed mechanism, of a head-forming support mounted on a shiftable fulcrum and capable of a compound movement whereby it may be positively moved toward the pointing mechanism and it may be raised or lifted somewhat on its return movement, casting head-forming dies mounted in the support for movement therewith, means for closing said head-forming dies and for opening the same prior to, or simultaneously with, the upward and return movement of the head-forming support, and means for giving the shiftable movement to said head-forming support, substantially as described.

8. In a nail-machine, the combination with shaping-dies, and a feed mechanism, of a head-forming lever, a slide mounted thereon, cooperating head-forming dies mounted on the lever and the slide respectively, means for actuating the slide to open and close said dies, and means for moving the head-forming lever to shift the position of the head-forming dies in a direction contrary to the line of feed of the work, substantially as described.

9. In a nail-machine, a head-forming lever, a slide movable thereon, and a retractor connecting the lever and the slide to impart relative movement to the same in opposite directions, and head-forming dies mounted on the lever and the slide respectively, and a cam having operative engagement with the lever and slide, in combination with shaping-dies, and means for moving the head-forming lever and the slide toward or from said shaping-dies, substantially as described.

10. In a nail-machine, the combination of a head-forming lever, a shiftable support for said head-forming lever, a slide limited to rectilinear movement on the head-forming lever, cooperating head-forming dies mounted on the lever and the slide respectively, a cam in operative relation to the lever and the slide, and a spring connecting the lever and slide, in combination with shaping-dies and means for imparting movement to the head-forming lever and the head-forming dies in a direction contrary to the line of feed of the work, substantially as described.

11. In a nail-machine, the combination of a head-forming lever provided

with roller-shoes 26, 27, a slide on said head-forming lever and provided with a roller-shoe 21, a cam disposed between the slide-dies and one die of the head-forming lever, another cam in operative relation in the other die of the head-forming lever, a retractor connecting the lever and the slide, cooperating head-forming dies mounted on the lever and the slide, a shiftable support for the head-forming lever, a set of shaping-dies, and a feed mechanism, substantially as described.

12. In a nail-machine, the combination of a head-forming lever, a swinging frame pivoted to the head-forming lever, means for adjustably supporting the swinging frame in pivotal relation to the head-forming lever, a set of head-forming dies carried by said head-forming lever, means for opening and closing said dies, a set of shaping-dies, and means for moving the head-forming lever and the head-forming dies toward or from the shaping-dies, substantially as described.

13. In a nail-machine, the combination of a head-forming lever, a shiftable support for said head-forming lever, two roller-shoes mounted on the lower portion of the head-forming lever, a cam having operative relation to one of said shoes, an adjustable plate, a spring connected to the head-forming lever and to said plate and adapted to normally position said roller-shoe in the path of said cam, a slide mounted on the head-forming lever and provided with a roller-shoe, another cam disposed between the roller-shoes of the lever and the slide, the cooperating head-forming dies on the lever and the slide, and a set of shaping-dies, substantially as described.

14. A nail-machine in which the pointing and heading devices are connected to two sets of dies, one set of dies carrying a non-shiftable position and opened or closed by cam-actuated devices, the other set of dies being provided with active faces arranged to point the nails by a compression action, a head-forming lever arranged to positively move one set of dies toward or from the other set, and a cam in operative relation to the head-forming lever, substantially as described.

15. In a nail-machine, the combination of a set of dies, another set of dies, cam-actuated means for opening and closing each set of dies, a head-forming lever arranged to positively advance one set of dies relative to the other set and at a period when both sets of dies are closed, a cam arranged to actuate the head-forming lever, and an intermittently-actuated feed mechanism operable to advance a wire during the period when both sets of dies are opened, such advancement of the wire being in a direction contrary to the heading movement of the set of dies by the head-forming lever, substantially as described.

16. In a nail-machine, the combination of two sets of independently-mounted dies, a main shaft having a plurality of cams, means actuated by certain cams to open and close said dies, a head-forming lever actuated by another cam and having means for feeding a wire through said dies when the latter are opened, and a head-forming lever actuated by a cam on said main shaft and operatively connected with one set of dies to positively move the latter in a direction contrary to the line of feed by the head-forming lever and at a period when both sets of dies are closed upon the wire, substantially as described.

17. In a nail-machine, the combination of a main shaft having a plurality of cams, an upright head-forming lever actuated by one of said cams and having means for gripping and heading a wire, an upright head-forming lever also arranged for actuation by one of said cams, two sets of dies independently mounted, one set being movable with the head-forming lever in a direction contrary to that of the wire under the action of the head-forming lever, and cam-actuated devices for opening and closing the dies of said sets, substantially as described.

701,179. DRAFT-EQUALIZER. WILLIAM C. DYER, Dallas, Tex. Filed Mar. 28, 1902. Serial No. 69,516. (No model.)

Claim.—1. A draft-equalizer comprising an adjustable bracket, a two-part equalizing-lever anchored pivotally together, an equalizing-bar

pivoted to the bracket and having a straight portion provided with a series of pivot-holes and a transversely-projecting portion, and the lever pivotedly connected to the outer end of the two-part lever with the said bar.

2. In a draft-equalizer the combination, with the bracket adapted to be adjustably connected to a cultivator-wheel axle, and the two-part equalizing-lever pivoted together and to the cultivator-beam, of an equalizing-bar pivoted in the bracket, and the lever connecting the said bar with the two-part lever.

3. In a draft-equalizer the combination, with the triangular bracket having a slot, and the equalizing-bar pivotally adjustable in said slot, of the two-part equalizing-lever, and the lever having diverging arms and connecting the two-part lever with the said bar.

4. The combination, with a disk pivot, of a double-draft equalizer adaptable for use from three to six horses, comprising a bracket capable of transverse adjustment on the pivot-axis, an equalizing-bar pivotally adjustable in the bracket, the two-part equalizing-lever pivoted together and to the pivot-beam, and having a hook or clevis, the double and single trees carried by the parts of said lever, the lever pivotally connecting the two-part lever with the said bar, and the double-tree attachment adapted to be connected to the said hook.

701,180. CLASP FOR TRACTION-WHEELS. RAIL SHIPLEY, Ravensport, Iowa, assignor to the Bettendorf Metal Wheel Company, a Corporation of Iowa. Filed Mar. 25, 1902. Serial No. 100,670. (No model.)

Claim.—1. A clasp for a traction-wheel adapted to be fastened to the rim of the wheel, and formed at its edge with a discontinuous longitudinally-extending projecting flange.

2. A clasp for a traction-wheel, comprising a flat body portion adapted to be fastened to the wheel-rim, and having at one edge an angular flange formed with alternate elevated and depressed portions.

3. A clasp for a traction-wheel comprising a base-plate adapted to be fastened to the rim of the wheel, and an integral angular flange at the edge of the base-plate cut away between its ends to form a depression.

4. A clasp for a traction-wheel comprising a base-plate adapted to be fastened to the rim of the wheel, and an angular flange at one edge, said flange being continuous at its base where it unites with the plate and having its outer projecting edge discontinuous.

5. A clasp for a traction-wheel comprising a flat body portion adapted to be fastened to the rim of the wheel, and having at one edge an integral projecting flange disposed at an angle to the body portion and formed at its edge with an open unobstructed recess.

6. In a wheel the combination with the rim, of a traction-clasp comprising a flat body portion fastened rigidly to the face of the rim and a flange disposed at right angles to the body and extending longitudinally thereof, and formed in its outer edge with an open free recess.

701,181. HUBBARD-CHAPER. MARSHALL E. HUBBARD and ARMAN L. LEVI, Patrons, N. J. Filed Feb. 4, 1902. Serial No. 92,002. (No model.)

Claim.—1. A hubbard-chaper comprising two separate members, each of which has one portion bent to form the chord of an arc and the other portion the circumference of the arc, the chord portions of the mem-

bers being rigidly connected and the arc portion being also rigidly connected, and means for rigidly locking one of their sliding connections while the other remains yielding, substantially as and for the purpose described.

2. A hubbard-chaper comprising two separate members, each of which has one portion bent to form the chord of an arc and the other portion the circumference of the arc, the chord portions having each a rigidly-attached terminal knocker with the knocker of each chord-portion embracing the body part of the opposite member, and a locking device for the sliding curved portions of the members, substantially as described.

3. A hubbard-chaper comprising two separate members, each of which has one portion bent to form the chord of an arc and the other portion the circumference of the arc, and having also at the head of these two portions a rearwardly-extending offset A' and B', sliding connections for the chord portions, sliding connections for the arc portions, and means for locking one of said sliding connections to a rigid adjustment substantially as shown and described.

4. A hubbard-chaper comprising two members united to form a curved front and a straight back, the members having their back portions rigidly connected and the front portions overlapping for adjustable attachment one to the other, and means for securing the front portions together, after the same have been adjusted, as set forth.

701,182. BROOM. FREDERICK J. BLAN and ARTHUR E. BLAN, London, Canada. Filed Feb. 27, 1902. Serial No. 92,021. (No model.)

Claim.—The combination with the broom-head, of the metallic band surrounding the head at or about the horizontal median line thereof, and having the lapped arms extending across the major portion of one side of the head, and terminating in the angular prongs b corresponding in length to the thickness of the head, and embedded therein, and the continuous connection extending from one edge of the head to the other, and passed to and fro through the head and lapped over the portions of the head at opposite sides of said band.

701,183. METHOD OF PREPARING FLAX FIBER FOR SPINNING. GEORGE H. BLAN, Chicago, Ill., assignor to Dearing Harvester Company, Chicago, Ill. Filed July 28, 1902. Serial No. 24,542. (No specimen.)

Claim.—1. The method of preparing flax fiber for spinning, which consists in separating and feeding the flax-stem endwise in bunches or wips, subjecting the bunches or wips to an initial or preparatory coarse rubbing overwise of the stem and feed thereby spreading the stem and loosening the fiber, and then subjecting the material to a continued crush-

ing and transverse breaking of the stem thereby breaking the woody center and separating the same from the fiber for the production of flax-drier, substantially as described.

2. The method of preparing flax fiber for spinning, which consists in separating and feeding the flax-stem endwise in bunches or wips, subjecting the bunches or wips to an initial or preparatory coarse rubbing overwise of the stem and feed thereby spreading the stem and loosening the fiber, then subjecting the material to a continued crushing and transverse breaking of the stem thereby breaking the woody center and separating the same from the fiber and then subjecting the material to a final or finishing pressing and spreading for the production of flax-drier, substantially as described.

3. The method of preparing flax fiber for spinning, which consists in separating and feeding the flax-stem endwise in bunches or wips, subjecting the bunches or wips to an initial or preparatory coarse rubbing overwise of the stem and feed thereby spreading the stem and loosening the fiber, then subjecting the material to a continued crushing and transverse breaking of the stem thereby breaking the woody center and separating the same from the fiber, then subjecting the material to a final or finishing pressing and spreading for the production of flax-drier, substantially as described.

4. The method of preparing flax fiber for spinning, which consists in subjecting untreated flax-stem endwise in bunches or wips to an initial or preparatory coarse rubbing overwise of the stem and feed thereby spreading the stem and loosening the fiber, then subjecting the material to a continued crushing and overwise breaking of the stem longitudinally thereby breaking the woody portion and separating the same from the fiber, then subjecting the material to a final or finishing pressing and spreading and then subjecting the drier as produced to repeated drawings and treating the drier during the drawings with oil, substantially as described.

5. The method of preparing flax fiber for spinning which consists in subjecting untreated flax-stem endwise in bunches or wips to an initial or preparatory coarse rubbing overwise of the stem and feed thereby spreading the stem and loosening the fiber, then subjecting the material to a continued crushing and overwise breaking of the stem thereby breaking the woody portion and separating the same from the fiber, then subjecting the material to a final or finishing pressing and spreading, then subjecting the drier as produced to repeated drawings, treating the drier during the drawings with oil, and applying water to the drier after oiling and during the drawings, substantially as described.

6. The method of preparing flax fiber for spinning, which consists in subjecting untreated flax-stem to rubbing, crushing, breaking and pressing, for separating the woody substance from the fiber and feeding the fiber into drier, then subjecting the drier to repeated drawings, treating the drier during the drawings with oil, applying water to the drier after oiling and during the drawings, and during the drier, after treatment with the oil and water, a sufficient length of time to cause the substance to become uniformly diffused through it, rendering it soft and flexible, and then subjecting the material and spread drier to a drawing treatment, substantially as described.

7. The method of preparing flax fiber for spinning, which consists in subjecting untreated flax-stem to rubbing, crushing, breaking and pressing, for separating the woody substance from the fiber and feeding the fiber into drier, then subjecting the drier to repeated drawings, treating the drier during the drawings with oil, applying water to the drier after oiling and during the drawings, and during the drier, after treatment with the oil and water, a sufficient length of time to cause the substance to become uniformly diffused through it, rendering it soft and flexible, and then subjecting the material and spread drier to a drawing treatment, substantially as described.

8. The method of preparing flax fiber for spinning which consists in feeding the flax into drier, subjecting the drier to a preparatory drawing, then subjecting the drier to a second drawing and during the second drawing treating the drier with oil and then subjecting the drier after treatment with oil to a third drawing and applying water to the drier during the third drawing, substantially as described.

701,184. THERMO-REGULATOR. JOHN B. BLANCHARD, Franklin, Iowa. Filed Sept. 12, 1901. Serial No. 73,004. (No model.)

Claim.—The combination with a clip having a vertical hooked end and a T-bar for fastening said end to the rearward end of the clip; of a recessed extension to the clip having grooves in the walls of the recess, a dial-rod, transverse thereto having in the grooves, a ball slightly unseated in the bottom of the recess, a camrod bent to said ball and fixed in the recess above the dial-rod, packing around to the camrod face of the ball-head and bearing upon the dial-rod, a contact mounted upon and engaging the dial-rod end of the ball, a handle extending laterally from the contact, a pawl pivoted to the bottom of the recessed extension and

engaging the contact, an arm to said pawl, a hand or grip thereon, and a projection for limiting the movement of the pawl in one direction.

701,185. ELECTROTHERAPEUTIC APPARATUS. GEORGE W. BLAN, Richmond, Va., assignor to Edwin C. Meyer, Richmond, Va. Filed Feb. 25, 1902. Serial No. 92,750. (No model.)

Claim.—1. In electrotherapeutic apparatus, the combination with a pair of alternating-current service-units, of a rotary converter connected to said units, and a combined voltmeter and automatic cut-out for limiting the voltage of the direct current from said converter.

2. The improved means for limiting the voltage of a source of electricity for therapeutic purposes, comprising a voltmeter measuring the voltage of the direct therapeutic current, an adjustable contact operated by said voltmeter, and a circuit-breaker operated through said contact.

3. In electrotherapeutic apparatus, the combination with a main alternating-current circuit, of a rotary converter operated by the current in said circuit, and means for automatically limiting the voltage of the direct current produced by said converter, said means comprising a voltmeter connected in said direct-current circuit, an adjustable contact operated by said voltmeter, and a circuit-breaker located in said alternating-current circuit and operated by the contact of said voltmeter.

4. The combination with a pair of alternating-current service-units, of a rotary converter connected thereto, a cycle-regulator connected in the alternating-current circuit of said converter, an electrotherapeutic apparatus connected in the direct and alternating current circuit of said converter.

5. The combination with a pair of alternating-current service-units, of a rotary converter connected thereto, a cycle-regulator comprising an adjustable shunting-coil connected in the alternating-current circuit of said converter, and electrotherapeutic apparatus connected in the direct and alternating current circuit of said converter.

6. In electrotherapeutic apparatus, the combination with a pair of alternating-current service-units, of a rotary converter connected to said units, and a pulsator operated by the direct current from said converter and adapted to produce pulsations of varying periods.

7. In electrotherapeutic apparatus, the combination with a pair of alternating-current service-mains, of a rotary converter connected to said mains, and a pulsator operated by the direct current from said converter and adapted to produce pulsations of varying periods, said pulsator comprising an induction-coil provided with a circuit-interrupter consisting of an oscillating contact-maker having an adjustable weight attached thereto.

8. In electrotherapeutic apparatus, the combination with a pair of alternating-current service-mains, of a rotary converter connected thereto, a flexible shaft and a coupling for connecting said shaft to said rotary converter.

9. In electrotherapeutic apparatus, the combination with a pair of alternating-current service-mains, of a rotary converter connected to said mains, and a rheostat connected in multiple with the direct-current terminals of said converter, substantially as and for the purposes herein specified.

701,186. APPARATUS FOR GENERATING GAS. WILLIAM J. FARRER, Chicago, Ill. Filed July 25, 1901. Serial No. 68,082. (No model.)

Claim.—1. In a gas-generating apparatus, a gas-generating chamber, a combustion-chamber, each apparatus provided with an inlet and an outlet for gaseous material and each chamber provided with a communicating passage-way through which molten material may flow, the gas-generating chamber provided with an outlet for gas and the combustion-chamber provided with an outlet for the products of combustion, means in the chambers, means to introduce gas-producing material into the gas-generating chamber, means to introduce fuel and means to introduce air to support combustion of the fuel into the combustion-chamber; whereby means are provided to supply gas-producing material to the gas-generating chamber and to exclude air therefrom, means are provided to supply fuel and air to support combustion thereof to the combustion-chamber, means are provided to supply molten material to the apparatus and to deliver molten material from the combustion-chamber into the gas-generating chamber and to thus maintain material in the gas-generating chamber at an operative gas-generating temperature; substantially as described.

2. In a gas-generating apparatus, a series of gas-generating chambers, a series of combustion-chambers, the gas-generating chambers respectively provided with outlets for gas and the combustion-chambers respectively provided with outlets for the products of combustion, and adjacent each a. each chamber provided with communicating passage-ways, molten material in the chambers, each chamber and communicating passage-ways arranged so that molten material may flow successively throughout and the passage-ways opening into the respective gas-generating chambers will be cooled by each molten material to exclude air from each gas-generating chamber, means to introduce gas-producing material into the gas-generating chambers, means to introduce fuel and means to introduce air to support combustion of the fuel, into the combustion-chambers; whereby, as gas is generated in the gas-generating chambers of the apparatus and thereby the heat of the molten material flowing through each chamber is reduced, each molten material is replaced by molten material of a higher temperature flowing thereto from the combustion-chambers of the apparatus; substantially as described.

3. In an apparatus for generating gas, the combination of a gas-generating chamber provided with an inlet and with an outlet for molten material and provided with an inlet for gas-producing material means to regulate the supply of gas-producing material delivered into the gas-generating chamber through the inlet therefor, and with an outlet for gas, with molten material to flow through the chamber; substantially as described.

4. In a gas-generating apparatus, the combination of a plurality of gas-generating chambers respectively sealed to exclude air therefrom and a combustion-chamber, each chamber provided with communicating passage-ways through which molten material may flow, each passage-way arranged so that the molten material shall cool the gas-generating chambers against the admission of air thereinto, the gas-generating chambers respectively provided with inlets for gas-producing material and with outlets for gas, and the combustion-chamber provided with means to introduce fuel and means to introduce a supporter of combustion thereto and with outlets for the products of the combustion thereof; substantially as described.

5. In a gas-generating apparatus, the combination of a series of gas-generating chambers and a series of combustion-chambers alternating therewith, the division-walls thereof being common thereto, each chamber provided with communicating passage-ways and each gas-generating chamber respectively provided with an inlet and with an outlet for molten material, with an inlet for gas-producing material and with an outlet for gas, and the combustion-chambers respectively provided with means to supply air to support combustion thereof and with outlets for the products of combustion, each outlet arranged in the division-walls with openings thereof adjacent to the outlets of the molten material in each combustion-chamber; substantially as described.

701,187. WASHING-MACHINE. WILLIAM S. FAVER, St. Louis, Mo. Filed Jan. 25, 1901. Serial No. 68,081. (No model.)

Claim.—1. In a washing-machine, the combination with a rubber, a shaft on which the same is mounted, and a pulley on said shaft, of a drive-shaft having an enlargement on one end thereof provided with a circumferential groove or channel, rollers lying within said groove or channel and on one end having a furled and embracing said enlargement, having projections thereon lying within said groove and provided with a rack adapted to engage said pulley, as and for the purposes set forth.

2. In a washing-machine, the combination with a rubber, a shaft on which the same is mounted and a pulley on said shaft, of a rotary drive-shaft having an enlargement on one end thereof provided with a circumferential groove or channel, rollers lying within said groove or channel on opposite sides thereof, and an arm having a furled end in which said rollers are mounted and provided with a segmental rack adapted to engage said pulley, as and for the purposes set forth.

3. In a washing-machine, the combination with a rubber, a shaft on which the same is mounted and a pulley on said shaft, of a rotary drive-shaft having an enlargement on one end thereof provided with a circumferential groove or channel, rollers lying within said groove or channel on opposite sides thereof, a rod or arm having a furled end in which said rollers are mounted and provided with a segmental rack upon its free end adapted to engage said pulley, and a horizontally-movable frame to which the furled end of said rod is pivoted, as and for the purposes set forth.

4. In a washing-machine, the combination with a rubber, a shaft on which the same is mounted and a pulley on said shaft, of a rotary drive-shaft having an enlargement on one end thereof provided with a circumferential groove or channel, means for adjusting the position of said en-

largement on said drive-shaft, rollers lying within said groove or channel, and an arm having a furled end in which said rollers are mounted and provided with a segmental rack adapted to engage said pulley, as and for the purposes set forth.

5. In a washing-machine, the combination with a rubber, a shaft on which the same is mounted and a pulley on said shaft, of a rotary drive-shaft having an enlargement on one end thereof provided with a circumferential groove or channel, a frame pivoted beneath said enlargement and capable of movement in a horizontal plane, the said frame having upwardly and outwardly extending arms thereon embracing said enlargement, a rod having a furled end on one end, the branches of which are pivoted to the arms of said frame and having a segmental rack on the opposite end adapted to engage said pulley, and rollers pivoted to the branches of said furled end, extending inwardly therefrom, and lying within said groove or channel on opposite sides thereof, as and for the purposes set forth.

6. In a washing-machine, the combination with a longitudinally-movable rubber-shaft, and means for actuating the same, of a rubber yieldingly mounted on said shaft, a stationary track having rollers thereon, and a projection on said rubber movable on said track, as and for the purposes set forth.

7. In a washing-machine, the combination with a rubber-shaft and means for actuating the same, of a rubber, a sleeve secured to said rubber and receiving said shaft, said sleeve being provided with elongated slots, a spring in said sleeve engaging the lower end of said shaft, a transverse pin extending through said shaft and slots, a stationary track having an irregular bearing-surface, and a laterally-projecting roller on said sleeve adapted to move upon said track.

701,188. FRUIT-JAR OR BOTTLE MACHINE. WILLIAM F. FARRER and HENRY F. LAMBERT, Chicago, Ill. Filed Oct. 24, 1900. Serial No. 64,170. (No model.)

Claim.—1. A glass-blowing machine, comprising an auxiliary support, a mold having a removable bottom and carried by the support, a plunger also carried by the said support and provided with means for admitting air therethrough into the mold, means for confining the support, and means controlled by the confining of the support for continuously reciprocating and rotating the plunger, as set forth.

2. A glass-blowing machine comprising an auxiliary support, a mold having a removable bottom and carried by the support, a plunger also carried by the support, a bellows valve-stem in the plunger and adapted to receive air from an air-blowing device, means for confining the support and means for continuously reciprocating and rotating the plunger, said means being controlled by the means for confining the support, as set forth.

3. In a glass-blowing machine, a table, a disk mounted thereon as to be overhanging the edge, a separable mold hinged to the disk and adapted to be inverted as the disk is rotated, the bottom of the mold being removable and adapted to engage with the parts of the mold and hold them

together, a plunger carried by the disk and means for continuously rotating the disk and reciprocating and rotating the plunger, substantially as described.

4. In a glass-blowing machine, a table, an auxiliary disk mounted thereon, a separable mold hinged at one end of the disk, the bottom of the mold being removable, a lever adjacent to the bottom of the mold, a stem from the bottom through the lever, means for moving said stem through the lever, and a hollow plunger adapted to enter the opposite end of the mold, substantially as described.

5. In a glass-blowing machine, a table, an auxiliary disk mounted thereon, a separable mold at one end of the disk and a plunger at the other, the bottom of the mold being removable and provided with guides and a notched part, a lever pivotedly secured to the disk adjacent to the bottom, the guides and the part passing through said lever, a rotary part upon the lever provided with a cam in position to engage with the notched part from the bottom of the mold, and a handle for operating said cam, substantially as described.

6. In a glass-blowing machine, a table, an auxiliary disk mounted thereon, a two-part mold hinged to one end of the disk and a plunger mounted upon the other end, the lower end of the mold being provided with a shoulder, a shoulder bottom detachably connected with the bottom of the mold, a swinging lever pivotedly secured to the disk and provided with means for moving the bottom toward and from the bottom of the mold, and an adjustable stop in position to engage with the lever and limit its movement when the shoulder of the bottom is in position to engage with the shoulder upon the lower end of the mold, substantially as described.

7. In a glass-blowing machine, a table, an auxiliary disk mounted thereon, a bracket secured near the center of the disk, a plate secured to the bracket and provided with grooves, a two-part mold hinged to the disk, each part being provided with a pin in position to be moved into said grooves, a removable bottom for the mold, and a rotary and reciprocating plunger mounted upon the disk with its axis coincident with the axis of the mold, substantially as described.

8. In a glass-blowing machine, a table, an auxiliary disk mounted thereon, one end of which is provided with a mold and the other end is provided with a rotary and longitudinally-movable plunger, means for confining the disk and means controlled by the means confining the disk for continuously rotating the plunger and moving it longitudinally, substantially as described.

9. In a glass-blowing machine, a table, an auxiliary disk mounted thereon, one end of which is provided with a mold and the other end is provided with an oscillatory and longitudinally-movable plunger, a piston and a transverse at the outer end of said plunger, and a segmental rack and cam for engaging with said piston and transverse respectively as the disk is oscillated, substantially as described.

10. In a glass-blowing machine, a table, an auxiliary disk mounted thereon provided with a mold at one end and a hollow plunger at the other, a piston loosely mounted against rotation upon the plunger near its outer end, a collar rigidly secured to the plunger beyond the piston and provided with a transverse, located upon the table, and two segments secured to said piston, one of which is provided with a rack for engaging with the piston and the other one is provided with a cam-shaped groove for engaging with the transverse upon the collar, substantially as described.

11. In a glass-blowing machine, a table, an auxiliary disk mounted thereon provided with a mold at one end and a hollow plunger at the other, the inner end of the plunger being provided with a head, a reciprocating valve-stem in the plunger, the outer end of which is provided with a mouthpiece, and the inner end is perforated and provided with a conical head, and yielding means for normally forcing said valve-stem outward, substantially as described.

12. In a glass-blowing machine, a table, an auxiliary disk mounted thereon, one end of which is provided with a mold and the other end with a rotary and longitudinally-movable hollow plunger, a bellows valve-stem through the plunger, the outer end of which is curved-shaped and provided with a mouthpiece and the inner end is perforated and provided with a conical head, a nut upon the curved-shaped portion of the stem, a spring between said nut and the end of the plunger, and means for continuously rotating the plunger and moving it longitudinally as the disk is oscillated, substantially as described.

13. In a glass-blowing machine, a support, a table rotatably mounted upon said shaft and provided with a series of glass-blowing mechanisms, each of said mechanisms being provided with a piston, a rack upon the table for each piston, and a cam-shaped track secured to the support in position to engage with the upper end of said rack and move them vertically as the table is rotated, and means for intermittently rotating the table, substantially as described.

14. In a glass-blowing machine, a support, a table rotatably mounted thereon, a series of glass-blowing mechanisms mounted upon the table,

each being provided with a piston, a reciprocating rack for each piston, the upper end of each of which is provided with an arm, a tank secured to the support and provided with cam-shaped grooves for engaging with said arms, and means for intermittently rotating the table, substantially as described.

15. In a glass-blowing machine, a column provided with a collar intermediate its length, a table rotatably mounted upon the column and provided with a hub which is adapted to be supported by said collar, a series of glass-blowing mechanisms mounted on the table and provided with means for operating them, a circular way secured to the hub of the table and provided with shoulders, one for each glass-blowing mechanism, and a motor provided with means for engaging said shoulders and intermittently rotating the way and the table, substantially as described.

16. In a glass-blowing machine, a column provided with a collar intermediate its length, a table rotatably mounted upon the column and provided with a hub which is supported by said collar, a series of glass-blowing mechanisms upon the table provided with means for operating them, brackets secured to the hub of the table, a circular way secured to said brackets, the lower edge of which is provided with notches, and a reciprocating motor provided with a pawl for engaging with said notches, substantially as described.

17. In a glass-blowing machine, a column, a table rotatably mounted thereon and provided with a series of glass-blowing mechanisms and means for operating the same, a shoulder way connected with said table, an air-cylinder pivoted thereto provided with a piston, a head upon the piston provided with a pawl for engaging with the shoulders of the way and intermittently rotating the table, substantially as described.

18. In a glass-blowing machine, a column, a table rotatably mounted thereon and provided with a series of glass-blowing mechanisms and means for operating the same, a circular shoulder way connected with the table, an air-cylinder pivoted thereto mounted adjacent thereto and provided with a piston, a head pivotedly mounted on the end of the piston, and a spring-actuated pawl in the head in position to engage with the shoulders of the way and intermittently rotate the table as the piston is reciprocated, substantially as described.

19. In a glass-blowing machine, a base, a column and a bracket mounted thereon, a table rotatably mounted on the column and provided with a series of glass-blowing mechanisms, a shoulder way connected with the table, an air-cylinder pivotedly mounted upon the bracket and provided with a piston, said cylinder being provided with two inlets and one outlet, and means between the end of the piston and the way for engaging with said shoulders and rotate the table, substantially as described.

20. In a glass-blowing machine, a support, a table mounted to revolve on said support, a shaft journaled in the table and carrying a piston, a mold and plunger carried by the shaft, a rack engaging the piston, and means for moving the rack as the table is revolved, as set forth.

21. In a glass-blowing machine, a support, a table mounted to revolve on the support, a shaft journaled in the table and provided with a piston, a mold and plunger carried by the shaft, a sliding rack engaging the piston and provided with a lateral arm at its upper end, and a cam-track on the support and with which the arm of the rack engages, as set forth.

701,189. LIFTING DEVICE. ALONSO E. FLETCHER, Worcester, Mass. Filed Jan. 14, 1908. Serial No. 58,919. (No model.)

Claim.—1. A lifting device comprising a body with a rear upwardly-projected terminal to form a grip, a member longitudinally slidable on the body in advance of the grip and provided with a rear finger-loop and front gripping extremities, and a pivoted catch slidably mounted on the body and independent of the said member.

2. A lifting device having a body with notches in the under portion thereof, a slidable member supported by the body and provided with gripping extremities and a rear engaging device, and a pivoted catch slidably

on the body and having a portion thereof adapted to engage the said notches, said catch being independent of the slidable member and free for individual adjustment.

3. A lifting device of the class set forth, comprising a body having lower notches and upwardly-projecting guide-loops, a member slidable in the said guide-loops and formed with outer gripping extremities and a rear engaging device, and a catch comprising a loop movable longitudinally in the said body and having a dog pivotedly supported thereby and formed with a front engaging lip and a rear nose to take into the said notches.

701,190. RABBIT-FINDER. GEORGE FERRIS, Westminster, England. Filed July 4, 1908. Serial No. 67,678. (No model.)

Claim.—1. In a rabbit-finder, a base member adapted to be used with a telescope, comprising a right bar and two similar prisms rigidly fixed to the bar with their corresponding faces parallel to each other but oppositely directed, each prism having four operative faces, two at right angles to each other and the other two equally inclined to the first and inclined at an angle of forty-five degrees to each other.

2. In a rabbit-finder, a base member, adapted to be used with a telescope, comprising a right straight tubular bar and two similar prisms rigidly fixed to the bar with their corresponding faces parallel to each other but oppositely directed, each prism having four operative faces, two at right angles to each other and the other two equally inclined to the first and inclined at an angle of forty-five degrees to each other.

3. In a rabbit-finder, a base member comprising a right straight tubular bar and two similar prisms rigidly fixed to the bar with their corresponding faces parallel to each other but oppositely directed, each prism having four operative faces, two at right angles to each other and the other two equally inclined to the first and inclined at an angle of forty-five degrees to each other combined with a mechanically separate binocular telescope having indicating devices in the eyepieces.

4. In a rabbit-finder, a base member comprising a right straight tubular bar and two similar prisms rigidly fixed to the bar with their corresponding faces parallel to each other but oppositely directed, each prism having four operative faces, two at right angles to each other and the other two equally inclined to the first and inclined at an angle of forty-five degrees to each other, combined with a mechanically separate binocular telescope having lenses rigidly in the eyepieces, indicating devices carried by the rings, means for changing the distance between the tubes, and means for locking the rings against rotation relatively to each other while permitting their distance apart to be varied.

5. In a binocular telescope for a rabbit-finder, the combination of two tubes, a pivot about which the tubes can turn relatively to each other, rings in the eyepieces, indicating devices carried by the rings and a connection between the rings locking them against rotation relatively to each other but allowing their distance apart to be varied.

6. In a binocular telescope for a rabbit-finder, the combination of two tubes, a pivot about which the tubes can turn relatively to each other, rings in the eyepieces, indicating devices carried by the rings, a tube fixed to each ring and a rod working loosely within this tube fixed to the other ring.

7. In a rabbit-finder, the base member comprising two right bars, a pivot connecting the bars, four similar prisms two rigidly fixed to each bar with their corresponding faces parallel to each other but oppositely directed each prism having four operative faces two at right angles to each other and the other two equally inclined to the first and inclined at an angle of forty-five degrees to each other.

8. In a rabbit-finder, the base member comprising two right bars, a pivot connecting the bars, four similar prisms two rigidly fixed to each bar with their corresponding faces parallel to each other but oppositely directed each prism having four operative faces two at right angles to each other and the other two equally inclined to the first and inclined at an angle of forty-five degrees to each other, combined with a mechanically separate binocular telescope having indicating devices in the eyepieces.

701,191. MACHINE FOR MAKING LUMBER. ALFRED E. FOWLER, Worcester, Mass. Filed Jan. 14, 1908. Serial No. 58,920. (No model.)

Claim.—1. In a machine for making lumber, a feeding mechanism to feed the work, two vibrating knives, mechanisms to vibrate the knives in opposition to each other and at right angles to the direction of the feeding of the work, combined with a turning surface in connection with each knife to turn the lip upward when formed by the knife, for the purpose set forth.

2. A machine for making lumber, having, in combination, a channeling-knife, and an edge-splitting knife normally in alignment transversely to the line of feed and means for drawing said knives out of their normal alignment during the operation of the machine to cause one knife to cut in advance of the other, substantially as described.

3. A machine for making lumber, having, in combination, a vibrating channeling-knife, arranged to cut transversely to the direction of the feed, a similarly-arranged vibrating edge-splitting-knife, and means for relatively and laterally changing the paths of motion of said knives during the operation of the machine, substantially as described.

4. A machine for making lumber, having, in combination, a channeling-knife, an edge-splitting knife, and means for relatively moving said knives in the direction of feed during the operation of the machine to change their relative cutting positions, substantially as described.

5. A machine for making lumber, having, in combination, a pair of opposed lip-turning devices adapted to simultaneously turn two lips on the surface of an incise and a support for said lips located between said devices, substantially as described.

6. A machine for making lumber, having, in combination, two lip-cutting knives acting to simultaneously cut two lips upon the surface of a sole, two opposed lip-turning devices acting to cut the lips out by said knives and a support for the lips between the lip-cutting devices, substantially as described.

7. A machine for making lumber, having, in combination, two opposed vibrating lip-cutting knives, acting transversely to the direction of the feed, and a feed-wheel acting on the sole between the lips cut by said knives, substantially as described.

701,192. MINERAL SUCKER. WILLIAM FRANK, Rochester, England. Filed Feb. 24, 1908. Serial No. 58,921. (No model.)

Claim.—1. In a mechanical sucker, a hopper for supplying the feed, a feed-roller mounted thereon, a plate for directing the feed to the feed-roller, and a feed-plate formed of a plurality of spring-actuated sections mounted in suitable relation to said feed-roller, substantially as shown and described.

2. In a mechanical sucker, in combination with a hopper for supplying the feed, a feed-roller mounted thereon, a plate for directing the feed to the feed-roller, a feed-plate formed of a plurality of movable sections and arranged in suitable relation to the feed-roller, means for operating the shock from the feed after its passage from the feed-plate, and mechanism for delivering the shock and feed separately to the fire.

3. In a mechanical sucker, a hopper for supplying the feed, a feed-roller mounted thereon, a plate for directing the feed to the feed-roller, a feed-plate formed of a plurality of sections and arranged in suitable relation to the feed-roller, a riddle arranged below the feed-plate for dividing the shock from the feed, and means for delivering the shock and feed separately to the fire.

4. In a mechanical sucker, the combination with a hopper for supplying the feed, a feed-roller mounted thereon, and a plate for directing the feed to the feed-roller, of a feed-plate constructed of a plurality of sections and arranged in suitable relation to the feed-roller, springs engaging the sections for normally retaining them in an elevated position, a riddle arranged below the feed-plate and adapted to separate the shock from the feed, a shock-receiver below the riddle, a shaft for expending the said receiver, means mounted in the receiver for delivering the shock over the fire, and means for delivering the larger feed to the fire.

5. In a mechanical sucker, the combination with a hopper for supplying the feed, a feed-roller mounted thereon and an inclined plate for directing the feed to the feed-roller, of a feed-plate constructed of a plurality of sections and arranged in suitable relation to the feed-roller, means for normally retaining the sections separately in an elevated position, a riddle mounted below the feed-plate for expending the shock from the larger feed, means for confining the riddle, a shaft below the riddle, a shock-receiver mounted upon the shaft and adapted to collect the shock as it falls, a pair of rotary star-wheels mounted in the shock-receiver and adapted to deliver the shock to the fire, means for rotating the said star-wheels, a reciprocating plate II fixed with doors and adapted to deliver the larger feed to the fire, and means for reciprocating the said plate II.

6. A mechanical sucker comprising in its construction a hopper for supplying the feed, a feed-roller arranged thereon, a plate for directing the feed to the feed-roller, a feed-plate constructed of a number of sections each capable of independent movement, springs for normally retaining the sections in an elevated position, a riddle mounted below the feed-plate and adapted to separate the shock from the larger feed, a plate for expending the riddle, a support for confining the riddle, a receiver mounted below the riddle and adapted to collect the shock, a shaft for expending the said receiver, a pair of rotary star-wheels driven by the said shaft and mounted in the shock-receiver to distribute the shock over the fire, two-armed gearing for rotating the star-wheels, an inclined plate I mounted upon the receiver and upon which the shock falls, means for confining the said plate I, an adjustable plate hinged to the said receiver, a reciprocating plate for receiving the larger feed, doors mounted upon the reciprocating

cutting plate H and moving therewith to push forward the feed, and means for reciprocating the said plate H.

7. In a mechanical shaker, the combination with a hopper, of a feed-plate mounted thereon formed of a plurality of independent movable sections, means for directing the feed to the said feed-plate, means for separating the shak from the large feed after its passage from the feed-plate, and mechanism for delivering the shak and large feed separately to the fire, substantially as herein shown and described.

8. In a mechanical shaker, the combination with a hopper for supplying the feed, a feed-roller mounted therein, means for directing the feed to the feed-roller, a feed-plate arranged in suitable relation to the feed-roller, means for separating the shak from the feed after its passage from the feed-plate, and mechanism for delivering the shak and large feed separately to the fire.

701,198. **RECK-ROTATING MECHANISM.** John F. FISHBURN, Montreal, Canada. Filed Apr. 15, 1901. Serial No. 24,989. (No model.)

Claim.—1. In a machine for pumping water and steam, a pump, a bearing therefor, means to slide said pump longitudinally in said bearing, mechanism for imparting an intermittent rotary motion to said pump, and means for throwing said mechanism into and out of connection with said pump.

2. In a machine for pumping water and steam, a pump, a rocking frame in which said pump is arranged to slide longitudinally, a rock-shaft that is said rocking frame, mechanism for rocking said shaft, and mechanism for imparting an intermittent rotary motion to said pump.

3. In a pumping-machine, a pump, a rocking frame in which said pump is arranged to slide longitudinally, a rock-shaft that is said rocking frame, mechanism for rocking said shaft, and mechanism for imparting an intermittent rotary motion to said pump.

4. In a pumping-machine, a pump, a rocking frame in which said pump is arranged to slide longitudinally, a rock-shaft that is said rocking frame, mechanism for rocking said shaft, and mechanism for imparting an intermittent rotary motion to said pump.

5. In a pumping-machine, a pump, a rock-shaft that is said pump, a pawl, and mechanism for throwing said pawl into and out of engagement with said rock-shaft.

6. In a pumping-machine, a pump, a rock-shaft that is said pump, a pawl, mechanism for imparting a reciprocating motion to one of said parts, and mechanism for throwing said pawl into and out of engagement with said rock-shaft.

7. In a pumping-machine, a pump, a rock-shaft that is said pump, two pawls arranged to engage said rock-shaft upon opposite sides thereof, and mechanism for throwing said pawls into and out of engagement with said rock-shaft.

8. In a pumping-machine, a pump, a rock-shaft that is said pump, a pawl, and a lever adapted to engage said pawl and throw it into and out of engagement with said rock-shaft.

701,194. **REVELLED TIE AND RAIL-JOINT CONNECTOR.** ORAN A. FRYE, Birmingham, Pa. Filed Sept. 24, 1901. Serial No. 24,989. (No model.)

Claim.—In combination with a metallic tie, a split-joint comprising an enlarged corrugated portion having connected each one of which is secured to the metallic tie, the upper face of said enlarged portion being cut away forming shoulders, said enlarged portion having a pair of openings formed therein one on each side of the rail-head, a locking fish-plate engaging one of said shoulders and one side of the rail head, web and base, an apertured lug on the under face of the said fish-plate and extending into one of said openings, a wedge engaging in said apertured lug and engaging the upper wall of the said opening formed in the enlarged portion, and locking-plate carrying an apertured lug on its under face engaging the other side of the rail-head and the other of said shoulders and having a wedge passed through said lug and engaging the upper wall of the said other opening in the enlarged portion, substantially as described.

701,195. **MEANS FOR SECURING HANDLES OR LEVERS TO TOOLS.** SAMUEL T. FISHBURN, Philadelphia, Pa., assignor to North Brothers Manufacturing Company, Philadelphia, Pa., a Corporation of Pennsylvania. Filed Feb. 27, 1901. Serial No. 24,989. (No model.)

Claim.—1. The combination is a tool in which the spindle extends in the handle or rest, of a spindle, a handle, a hub secured to the handle and into which the spindle extends, a cap mounted between the hub and a shoulder on the spindle, with a series of antifriction-balls between the cap and the hub, substantially as described.

2. The combination of a spindle, a handle or rest, a flanged hub secured to the handle or rest, a sleeve forced into one end of the hub, a block forced into the opposite end of the hub, the spindle extending through the block and the sleeve, and means for preventing longitudinal movement of the spindle, substantially as described.

3. The combination of a spindle, a handle or rest, a hub, an external flange at one end of the hub, said flange being secured to the handle or rest, an internal flange at the opposite end, a sleeve within the hub resting against the internal flange and reduced to fit the spindle, a block inserted within the opposite end of the hub and resting against the internal flange, the spindle passing through the block in the sleeve, and means for preventing longitudinal movement of the spindle, substantially as described.

4. The combination of a spindle having a reduced portion, a handle or rest, a hub having an internal flange secured to the handle or rest and having an internal flange at the opposite end, a sleeve inserted in the

hub and resting against the internal flange and reduced at the opposite end to fit the reduced portion of the spindle, a shoulder block inserted in the hub and resting against the internal flange, a cap resting against a shoulder on the spindle, a series of balls between the cap and the block, and a nut on the end of the spindle confining the spindle longitudinally but allowing it to freely rotate, substantially as described.

701,196. **RAIL-CARTER.** THOMAS GALVIN, Detroit, Mich. Filed May 14, 1901. Serial No. 24,989. (No model.)

Claim.—1. In a rail-carter, a large ball, a socket having two jaws embracing the ball and divided vertically into two parts, means for moving said parts to each other, a circular channel in each of said jaws, and small balls in said channels and engaging opposite sides of the large ball, substantially as described.

2. In a rail-carter, a large ball, a socket having jaws embracing the ball, and divided vertically into two parts, means for moving said parts to each other, circular channels in the jaws, small balls in said channels and engaging opposite sides of the large ball, and supplemental balls in recesses in the socket and engaging the upper side of the large ball, substantially as described.

701,197. **DOUBLE ENDING-BOARD.** JOHN E. GARDNER and JAMES F. ADAMS, Baltimore, Ohio; said Gardner assignor to said Adams. Filed Sept. 21, 1901. Serial No. 24,989. (No model.)

Claim.—1. In a double ending-board, two pressing-boards, quadrangular spring-loops held to each on one board, two elongated guides secured near side edges on the other board, the spring-loops engaging with said guides, and means substantially as described for causing said spring-loops angularly disposed between the boards so as to cutably open the boards apart.

2. The combination with two quadrangular spring-loops loosely held on one pressing-board, guides longitudinally disposed near side edges of the other board, cross-bars of the spring-loops engaging beneath the guides, and adjustable means to define the degree of inclination given to the spring-loops for cutably opening apart the two pressing-boards.

3. The combination with two pressing-boards, two spring-loops held to rest on one of the pressing-boards, and guides on the other pressing-board loosely engaged by the opposite ends of the spring-loops, of coating means adjustable from one pressing-board and loosely engaging the guides, and means for moving the spring-loops and means adjusted to space apart the pressing-boards.

4. The combination with two pressing-boards, two rectangular spring-loops held to rest on one of the pressing-boards by one end of each loop, and two longitudinally-disposed parallel guides secured on the other pressing-board and loosely engaged by opposite ends of the spring-loops, of two spaced and coating means adjustably held on one of the pressing-boards and engaging the guides, a slidable bumper-piece on one of the pressing-boards adapted to press upon the free end of one of the loops and an adjacent end of one of the spring-loops, and a two-button adapted to bear upon the bumper-piece to hold it folded on the pressing-board.

701,198. **CAKE-PAN.** HARRY A. GRAVE, St. Anthony, Minn. Filed Aug. 24, 1901. Serial No. 24,989. (No model.)

Claim.—The combination with a body having an open side, flanges extending from the remaining sides, and a connecting-strip, of a member

slide bottom adapted to rest upon the flanges and strip, a side flange, grooved extensions to said side adapted to receive the free ends of the sides of the body, means pivoted to said free ends and adapted to engage the extensions, and a frame detachably secured to and extending over the body.

701,199. **SHOULDER FASTENER.** LOUIS H. HANCOCK, Fargo, N. D. Filed Nov. 24, 1901. Serial No. 24,989. (No model.)

Claim.—1. A fastener for lacing-strings comprising a tubular body having open ends and adapted to be secured to a shoe or other article, a plate-spring secured at its lower end and extending upwardly through the tubular body and over the upper end of the shoe, teeth or prongs at the upper end of the plate-spring adjacent to the upper edge of the tubular body, and a spring adapted to move the teeth or prongs of the plate-spring toward the outer face of the tubular body.

2. A fastener for laces or strings consisting of an open-ended tubular body, having a transverse slot or opening in its front face and adapted to be secured to a shoe-upper or other article, a plate-spring secured at its lower end and extending upwardly through said tubular body and having a bent-over upper end, teeth or prongs at the end of said bent-over portion, a coiled spring secured at one end to the inner face of the tubular body, said coiled spring provided with an extension clamping the plate-spring and extending transversely across the front face of the tubular body within the slot in the shoe.

3. A fastener for laces or strings consisting of a base-plate adapted to be secured to a shoe-upper or other article, an open-ended tubular body secured to said base-plate and having a transverse slot in its front face, a plate-spring secured at its lower end to the base-plate and extending upwardly through the tubular body and bent at its upper end, teeth or prongs at the end of said bent portion adjacent to the upper end of said tubular body, a wire spring secured at one end to the inner face of the tubular body having contractile cells extending across the tube, a straight portion bent transversely from the coiled portion, through the slot in the tubular body, a band and a second straight transverse portion extending in an opposite direction from the first straight portion which with the said first straight portion forms a clamp for the plate-spring and forms a finger-piece for operating the device, substantially as shown and described.

4. A fastener for laces or strings consisting of an open-ended tubular body adapted to be secured to a shoe-upper or other article, a transverse slot in the front face of the tubular body, a plate-spring secured at its lower end, said spring extending upwardly through the tubular body and having a bent-over upper portion provided with teeth or prongs at its end, a wire spring secured at one end to the inner face of the tubular body, contractile cells formed therein, said wire spring having straight transverse oppositely-extending arms adapted to grip the plate-spring between them, and lying in said transverse slot, substantially as shown and described.

5. A fastener for laces and strings consisting of an open-ended tubular body adapted to be secured to a shoe-upper or other article, a plate-spring secured at the lower end, and having the upper end bent over and provided with teeth or prongs adapted to bear against the front face of the tubular body adjacent to its upper edge and means for moving said teeth against the upper portion of the tubular body adjacent to the edge thereof.

701,200. **TIE-BEAKER.** HENRY J. BRUNSWOLD and ALBERT E. ADAMS, High Springs, Fla. Filed Apr. 23, 1901. Serial No. 24,989. (No model.)

Claim.—1. In a tie-beaker, a ring composed of tubular sections, T connections between said sections and threaded thereon, inwardly-projecting members or bumpers on said connections, and the said having clamps holding said ring whereby it may be supported in an upright position substantially as set forth.

2. A tie-beaking ring composed of a series of tubular sections, a series of members, and means for connecting the tubular sections and members

whereby sections and members may be added or removed to vary the size of the ring substantially as set forth.

701,201. SAW-HANDLE FASTENING. HARRISON E. HARRIS. Merriam, N. H. Filed Aug. 9, 1901. Serial No. 71,510. (No model.)

Claim.—1. A saw-handle fastening, comprising a slotted tube having a concave-convex end to form impinging edges for engagement with the saw, a bar arranged within the tube and adapted to bear against the top of the saw, and means for forcing said bar in rigid contact with the saw.

2. A saw-handle fastening comprising a slotted tube having impinging edges at its lower end, a saw seated in said slot and engaged by the impinging edges, means pivotally mounted in said tube for engaging the saw and means for holding the engaging member in contact with the saw.

3. A saw-handle fastening comprising a tube having a vertical slit therein, a concave-convex portion in said tube, the edges of which are adapted to bear against the lower edge of the saw, and a lever for holding said saw in engagement with said edges.

4. In a saw-handle fastening, the combination with a slotted tube, of a saw seated therein, a pivoted and sliding bar adapted to engage one edge of the saw, said bar being provided with a cam-face, and an eccentrically-mounted lever pivoted above said bar and adapted to engage the same to normally hold it in rigid contact with the saw.

701,202. SAFETY-PLATFORM FOR RAILWAY-CARS. JOHN HOLLAND and WILLIAM F. WHEELER, San Antonio, Tex. Filed Oct. 23, 1901. Serial No. 72,732. (No model.)

Claim.—1. A car-platform including a plurality of independently-yieldable members arranged side by side to form a continuous structure.

2. A car-platform including a plurality of independently-movable members arranged side by side to form a continuous structure and springs acting against the respective members.

3. A car-platform including a plurality of independently-yieldable members arranged side by side to form a continuous structure, said members being of different widths.

4. A car-platform consisting of two sections separated by a space to receive a coupling, and each section consisting of a plurality of independently-yieldable members arranged side by side to form a continuous structure.

5. A car-platform including a plurality of members, cross-bars adapted to receive said members, cheeks on said members, a cross-bar to receive said cheeks, and coiled springs on said cheeks bearing against said members and last-mentioned cross-bar.

701,203. FUSE-IGNITER. CHARLES E. JENNIS and JOHN J. McNEAL, South Little Rock. Filed Nov. 13, 1901. Serial No. 82,154. (No model.)

Claim.—1. A fuse-igniter comprising a shell containing fusible material and attaching means on said shell for connecting said shell to the ends of a bunch of fuses, whereby the same are protected and caused to be simultaneously ignited.

2. A fuse-igniter comprising a shell containing fusible material, and a wire secured to said shell for connecting the same to a bunch of fuses, whereby the same are protected and caused to be simultaneously ignited.

3. A fuse-igniter, comprising a shell having its upper end closed and containing a mass of fusible substance, a disk of open-work material for retaining said fusible substance in place, and means for connecting said shell to the ends of a bunch of fuses, whereby the same are protected and caused to be simultaneously ignited.

4. A fuse-igniter, comprising a shell having its upper end closed, provided with an annular groove on its inner surface and containing a mass of fusible substance, a disk of open-work material fitting within said groove for retaining said fusible substance in place, and attaching means for connecting said shell to the ends of a bunch of fuses, whereby the same are protected and caused to be simultaneously ignited.

5. A fuse-igniter comprising a cone-shaped shell containing a fusible substance and having a groove on its inner surface, a disk of open-work material held in place by said groove, and a wire secured to said shell below said disk for connecting said shell to the ends of a bunch of fuses, whereby the same are protected and caused to be simultaneously ignited.

6. A fuse-igniter comprising a cone-shaped shell containing a fusible substance and having a groove on its inner surface, a disk of open-work material held in place by said groove, a disk of combustible water-proof material in said shell beneath said fusible substance, and a wire secured to said shell for connecting the same to the ends of a bunch of fuses, whereby the same are protected and caused to be simultaneously ignited.

701,204. EXHAUST MECHANISM. THOMAS D. ELAM, Savannah, Ga. Filed Oct. 3, 1901. Serial No. 77,821. (No model.)

Claim.—1. In an exhaust mechanism for locomotives, the combination with a main exhaust-flue, of an auxiliary exhaust-flue opening at its lower end at one side of the main flue and gradually enlarging circumferentially

centrally around said main flue above its lower inlet end, and means controlling the auxiliary flue, substantially as set forth.

2. The combination is an exhaust mechanism substantially as described, of a main exhaust-flue, and a side exhaust-flue opening at its lower end laterally to the main flue and gradually widening circumferentially above said opening, substantially as set forth.

3. The combination of the main exhaust-flue, the supplemental or auxiliary exhaust-flue arranged alongside the main flue and controlling the same at its upper end and gradually reducing to an opening lateral to the main flue at the lower end of the auxiliary flue whereby there are provided two concentric nozzles at the upper end of the regulator and a reduced auxiliary flue-opening at the lower end of the main flue, and a valve controlling the auxiliary exhaust-flue, substantially as set forth.

4. The combination is an exhaust mechanism of the main or body portion, the intermediate chamber, the exhaust-nozzle above the said chamber and in communication at their lower ends therewith, said nozzle being composed of an inner or control nozzle and an outer nozzle enclosing the inner nozzle at its upper end and gradually reducing toward its lower end and opening at said end laterally to the inner nozzle, and a valve controlling the lower end of the auxiliary nozzle, substantially as set forth.

5. An apparatus substantially as described comprising the main or body portion circular in cross-section, the intermediate chamber rectangular in cross-section and extending laterally beyond the circumference of the body portion, the main flue in line with the body portion, the supplemental or auxiliary flue having a circular upper portion enclosing the orifice of the main flue and gradually narrowing toward its lower end and communicating at such end with the upper end of the lateral extension of the intermediate chamber, and the valve controlling the lower end of the supplemental flue, substantially as set forth.

6. An exhaust mechanism comprising the main flue, the supplemental or exhaust flue, enclosing the main flue at its upper end and having an inlet-opening at its lower end and gradually converging or narrowing from its upper circular portion toward such inlet-opening substantially as set forth.

701,205. AIR-BRAKE FOR RAILWAY-CARS. FREDERICK M. KIRBY, South Bethlehem, Pa. assignor to WILLIAM H. MILLER and WILLIAM J. REA, South Bethlehem, Pa. Filed Aug. 12, 1901. Serial No. 72,617. (No model.)

Claim.—In a device of the character described, the combination of two pipes formed at their ends with projecting lips and adjacent recesses to receive the former, said pipes adapted to run one upon the other and having curved inner walls with registering apertures therein, also loosely mounted in the said inner walls adjacent the said apertures, and held against the pipes, the inner surfaces of which normally bear thereagainst, yokes on the pipes, a spring pivotally carried by each yoke, and clips for engaging the springs.

701,206. VOTING-MACHINE. GEORGE W. LAFRANK, Franklin County, Va. Filed Aug. 20, 1901. Serial No. 73,092. (No model.)

Claim.—1. A voting-machine substantially as herein described, comprising the casing or housing, having the two compartments, the registering mechanism in one of the compartments, an operating-shaft geared with the registering mechanism and provided with means for operating the alarm-bell, and with a crank-arm, an alarm-bell and its hammer arranged for operation by the main shaft, the taking device, the upright slides carrying the same, the guides in the casing for said upright slides, the rocking frame for operating the slides and connected with the crank-arm of the drive-shaft, the rollers supporting the ballot-sheet, one of said rollers being geared with the registering mechanism, the plates or guide-bars over which the ballot-sheet is directed, the ink-bar arranged to supply the taking device, and the independent type-bar arranged to be operated to print upon the ballot-sheet passed over the plates-bar, substantially as set forth.

2. The combination of the plates or guide-bars for the ballot-sheet, the printing device, the ink-carrier, the guides in the casing, the slides operating in said guides, the taking device carried by said slides, the rocking frame engaged with the slides and means for operating the rocking frame, substantially as set forth.

3. The combination of the rollers for supporting the ballot-sheet, the printing device, the taking device including slides, and a rocking frame for operating the same, and means for advancing the ballot-sheet and for operating the rocking frame simultaneously, substantially as set forth.

4. The combination with the register, the rocking frame, the sliding taking device carried by the rocking frame, the printing device and the means for supporting the ballot-sheet, of gearing between the ballot-supporting means and the register, and the main shaft geared with the register and having a crank-arm connected with the rocking frame, substantially as set forth.

5. In a voting-machine the combination of the rollers for supporting the ballot-sheet, the plates or guide-bars for the ballot-sheet, the printing-levers, the ink-carrier, the taking-brush movable between said carrier, and the types of the lower, the slides carrying said brush, the guides for said slides, the rocking frame engaging said slides, and the main shaft connected with said rocking frame, and gearing between the said shaft and one of the rollers supporting the ballot-sheet, substantially as set forth.

701,207. TRANSFERRING CAR OR TRUCK. BENJAMIN A. LARLEY, Hartford, Cal. assignor of one-half to HENRY LADLOW, Hartford, Cal. Filed Mar. 1, 1902. Serial No. 64,205. (No model.)

Claim.—1. In a device of the class set forth, the combination of a bed or body having crank-axles movably attached thereto and provided with wheels, a two-table attached to the bed or body at a point between the axles, and means for disengaging with the said axles to throw the wheels out of engagement with the ground or other surface and at the same time bring the two-table into operative position.

2. In a device of the class set forth, the combination of a bed, a draft device pivotally connected to the front extremity of said bed, crank-axles movably attached to the under side of the bed and having wheels thereon, and link-bars movably attached to the crank-axles and to the said draft device.

701,208. CABLE CONNECTION. CHARLES LARK, Milford, Conn., assignor to the New Haven Novelty Machine Company, New Haven, Conn. Filed Jan. 10, 1902. Serial No. 93,942. (No model.)

Claim.—1. A connection for a pipe-covered cable, comprising a tubular body to insulate the splice, and means at the opposite ends of said body to clamp the inner and outer sides of the pipe-covering water and air tight.

2. In a connection for pipe-covered cable, means to clamp the inner and outer sides of the ends of the lead pipe covering the cable water and air tight, a tubular body surrounding and connecting said clamping means, and a screw-threaded nut to retain said tubular body in position to cover the splice water and air tight.

3. A connection for covered cable, comprising means to clamp water and air tight the covering for one cable, an extension having a branch, means to connect the covering of two cables water and air tight with one end of said extension and the branch, and a tubular body coating with said extension and the means employed for clamping the covering of another cable, to make the means clamping the end of the cable water and air tight with said extension.

4. A connection for pipe-covered cables, comprising pipe-clamping means composed of two members to embrace the ends of the pipe between them, and a sleeve joining said pipe-clamping means and protecting the spliced wires between the ends of the pipe.

5. A connection for a pipe-covered cable comprising means to clamp the ends of the pipe, and a tubular sleeve having an interior diameter greater than the exterior diameter of the means for clamping the pipe whereby the sleeve may be slid longitudinally over the pipe-clamping means and pipe.

6. In a connection for a plurality of covered cables, metallic collars surrounding the covering of each cable near its end, a metallic sleeve, and a connected extension having a branch for the reception of wires of a cable to be led off laterally from the main cable, and means at the outer end of said sleeve and at one end of the extension and its branch to engage the said collar and complete a water-tight joint between the covering of said cable to protect the junction of the wires thereof from water and moisture.

701,209. COVERING MEANS FOR JOINTS IN ELECTRIC CABLES. CHARLES LARK, Milford, Conn., assignor to the New Haven Novelty Machine Company, New Haven, Conn. Filed Mar. 10, 1902. Serial No. 97,002. (No model.)

Claim.—1. Covering means for spliced joints of sheathed cables, comprising a sleeve having extended fixed hubs embracing the sheath of each cable at opposite sides of the junction of the ends of the wires of the cable, leaving the ends of the sheaths inside the sleeve that said ends and the wires of the cables may be insulated by an insulating medium run into the sleeve.

2. Covering means for spliced joints of sheathed cables, comprising a sleeve having extended fixed hubs embracing the sheath of each cable at opposite sides of the junction of the ends of the wires of the cable, leaving the ends of the sheaths inside the sleeve that said ends and the wires of the cables may be insulated by an insulating medium run into the sleeve, the ends of said hubs being insetted and soldered to the sheaths of the cables.

3. Covering means for spliced joints of sheathed cables, comprising a sleeve having extended fixed hubs to embrace the sheaths of the cables at opposite sides the junction of the ends of the wires of the cables, and locking means to affix the hubs to the sheaths of the cables outside the ends of the sleeve.

4. Covering means for the spliced ends of wire cables, comprising a sleeve, a hub fixed in one end of the sleeve and to the cable inside the sleeve, and an insulating medium run into said sleeve and surrounding said spliced ends and the end of the covering of the cable inside the sleeve.

701,210. CABLE CONNECTION FOR COVERING SPLICED JOINTS. CHARLES LARK, Milford, Conn., assignor to the New Haven Novelty Machine Company, New Haven, Conn. Filed Mar. 10, 1902. Serial No. 97,002. (No model.)

Claim.—1. A cable connection to cover a splice therein, comprising externally-threaded hubs embracing the lead pipes of the two cables to be united, said hubs being soldered to said pipes, one of said hubs having an external flange 2; a sleeve having a collar at each end, one of said collars having at its outer end a screw-thread to engage the screw-thread of one of said hubs, and the other having at its outer end an internal flange, a packing-ring retained at one side by said internal flange, and acted upon at its other side by said external flange, and a running-nut applied to the hub having the external flange.

2. In a cable connection for lead pipes, hubs having inclined outer ends surrounding and soldered to said pipes, and a device to engage both said hubs to prevent the separation of the lead pipes.

3. In a coupling for lead pipes, hubs having inclined outer ends surrounding and soldered to said pipes, said hubs being cut away at their lower sides to enable either to pass between the interior of the hubs and the exterior of the pipes, and a device to engage both said hubs and prevent the longitudinal movement of one of said pipes with relation to another of said pipes.

4. In a lead-covered cable connection, hubs soldered to the lead covering of the cables to be united, a sleeve having at one end a threaded collar united by screw-threads to one of said hubs, said sleeve having at its opposite end a collar having an internal flange and embracing loosely the other of said hubs, a lead washer surrounding the latter hub and interposed between the interior of the collar surrounding one end of the sleeve and between an internal flange of said collar and an external flange of said hub, said washer being held snugly at both its sides and of its outer and inner edges against drawing, and a nut to clamp said washer tightly in its operative position.

5. A connection for spliced cables comprising a hub having its outer end beveled outwardly and soldered to the exterior of the cover of one cable back from the end thereof, and a sleeve embracing said hub and insulating the splicing of the wires of the cables.

701,211. ELECTROMAGNETIC PATTERN-CONTROLLING APPARATUS FOR LOOMS. ARTHUR P. S. MACMURRAY, Chicago, Ill. Filed Apr. 10, 1902. Serial No. 102,001. (No model.)

Claim.—1. In a loom pattern mechanism, the cable-wires, the reader-wires, and intermediate wires soldered to the cable-wires, a hub

having strung upon it washers each insulated on the one side, and means of pressing the washers toward each other so as to clamp between each pair, an intermediate and a reader wire, substantially as and for the purpose set forth.

2. In a loam-pattern mechanism, the combination of the intermediate wires, the cable-wires, the reader and its clamp, the washers and bar for clamping the reader-wires to the intermediate wires, and the layers of insulated sheets having the cable-wires held between pairs of them, the intermediate wires being connected to the cable-wires, substantially as described.

701,212. AMALGAMATOR. JOHN S. MARSHALL and PETER J. WILSON, Baltimore, Md. Filed Aug. 27, 1901. Serial No. 74,847. (No model.)

Claim.—1. In an amalgamator the combination with a tank or receptacle, provided with an amalgam-receptacle at its bottom having a central discharge-opening, of a revolvable agitator within the tank, a plurality of overflow-traps communicating with the upper portion of the tank, a shaft extending through a plurality of said traps and agitators on said shaft within the traps.

2. In an amalgamator, the combination with a tank having an amalgam-receptacle at its bottom, of a discharge-pipe provided with two independent valves, a revolvable agitator within the tank, a plurality of overflow-traps communicating with the tank, a shaft extending through the traps, agitators upon said shaft, and a supplemental box or tank containing an agitator and adapted to receive the discharge from said traps.

3. In an amalgamator, the combination with a tank having an amalgam-receptacle at its bottom, of a discharge-pipe for said receptacle having two independent valves, a series of overflow-traps communicating with the rear side of the tank and a second series of traps communicating with the front side of the tank, all of said traps being connected to a common discharge-trap which delivers to an auxiliary tank, and revolvable agitators within said traps.

4. In an amalgamator, the combination with a tank having a converging bottom provided with a central discharge-opening, a pipe communicating with said opening and provided with two independent valves, a revolvable main shaft extending through said tank, perforated agitator-blades projecting from the shaft, a series of overflow-traps communicating with the rear side of the tank, another series of overflow-traps communicating with the front side of the tank, a shaft extending through each series of the traps and carrying agitators within the traps, means for revolving these shafts from the main shaft, pipes connecting all of said traps with a discharge-trap, inlet and outlet cocks for said traps, and an auxiliary tank provided with an agitator and a discharge-pipe having two independent valves.

701,213. FRUIT-JAR. FRANKLIN HANCOCK, Danversport, Iowa. Filed Oct. 25, 1901. Serial No. 75,304. (No model.)

Claim.—The combination with a jar having a neck of considerable depth and provided with an inner lower conical shoulder and an upper outer flange, of a cap having a central upwardly-extending projection with a bearing-cavity therein and a lower bearing edge, a rubber gasket interposed between said bearing edge and shoulder, a fastening device consisting of a longitudinally-slotted bar having lower transversely-disposed terminal hooks to removably engage the flange of the neck and also provided with central depending ears and end sockets on its upper side, and a lever having a cam-head slidably between the ears and adapted to move a portion thereof extend below said ears to engage the bearing-cavity in the central projection of the cap, the outer end of said lever being adapted to enter the sockets at the ends of the slotted bar, substantially as described.

701,214. CONDUIT. THOMAS J. MILLER, Denver, Colo. Filed Apr. 6, 1901. Serial No. 54,730. (No model.)

Claim.—1. A conduit composed of sections, bands or rings T-shaped in cross-section surrounding the conduit at the joints, and having interiorly-projecting, circumferential tongues adapted to pass between the sections at each joint, a packing material located between the tongues and the sections and held in place by the band, and tie-rods connecting the bands.

2. A conduit composed of sections, bands or rings surrounding the

conduct at the joints, and T-shaped in cross-section, an interior circumferential tongue being formed on the ring, adapted to pass between the ends of the sections, the body of the band overlapping the sections exteriorly, the band being provided with exteriorly-projecting, apertured lugs, and the ends attached to the lugs for connecting the conduct-sections.

3. A conduct composed of sections, bands located at the end joints and provided with interiorly-projecting circumferential tongues located between the extremities of the sections, the exterior portions of the bands overlapping the sections, a packing co-operating with the bands to form a tight joint, a circular recess being left between the sections at the inner periphery of the tongue of the band, and a cement filling for said recess.

4. A conduct composed of sections, a band or ring, T-shaped in cross-section located at the joints of the sections, the body of each band overlapping the section ends exteriorly and the tongue passing between the ends of the sections, the band being provided with exterior openings on opposite sides of the tongue, and a cavity being left between the band and the conduct into which molten metal or other packing may be introduced through the said openings.

5. A band for sectional pipes or conduits, said band being T-shaped in cross-section whereby a circumferential tongue is formed on its inner periphery, its outer periphery having a plurality of apertured lugs.

701,215. METHOD OF OBTAINING SINE BY ELECTROLYSIS.
LEWIS MOSE, London, England. Filed Aug. 12, 1901. Serial No. 71,778. (No specimen.)

Claim.—A method of obtaining sine in a solid metallic condition which consists in depositing the sine on separate cathodes by electrolysis and simultaneously therewith subjecting the deposited sine upon one cathode to a longitudinal and transverse rubbing action of the sine deposited upon the other cathode under pressure.

701,216. APPARATUS FOR OBTAINING SINE BY ELECTROLYSIS.
SEE LEWIS MOSE, London, England. Filed Mar. 4, 1902. Serial No. 90,601. (No model.)

Claim.—1. In apparatus for obtaining sine by electrolysis, the combination of a number of cylindrical cathodes rotating in contact with each other within an electrolytic bath, means for pressing the cylinders against each other and means for producing a longitudinal rubbing action between the cylinders, substantially as described.

2. In apparatus for obtaining sine by electrolysis, the combination of a number of cylindrical cathodes rotating in contact with each other within an electrolytic bath, means for pressing the cylinders against each other and means for producing a longitudinal rubbing action between the cylinders, substantially as described.

3. In apparatus for obtaining sine by electrolysis, the combination of a number of cylindrical cathodes rotating in contact with each other within an electrolytic bath, means for pressing the cylinders against each other, means for driving the one cylinder by external power which cylinder gives rotation to the others by frictional contact, and means for producing a longitudinal rubbing action between the cylinders, substantially as described.

4. In apparatus for obtaining sine by electrolysis, the combination of a number of cylindrical cathodes rotating in contact with each other within an electrolytic bath, means for pressing the cylinders against each other and means for imparting a longitudinal to-and-fro motion to some

or all of the cylinders for producing a rubbing action between them, substantially as described.

5. In apparatus for obtaining sine by electrolysis, the combination in an electrolytic bath of a number of rotating horizontal cylindrical cathodes each differing somewhat in diameter from that or these next to it, pressed toward each other by means which allow their axes to move further apart, all these axes being mounted in sliding bearings, and one of the axes of each alternate cathode being provided with a stud engaged in an inclined groove in its bearing, so that as each cathode revolves, it is moved to and fro longitudinally, substantially as and for the purpose set forth.

701,217. APPARATUS FOR ELLIPTICAL TURNING AND BORING.
CHARLES J. MONTAGNA, Rouen, France. Filed Sept. 2, 1901. Serial No. 74,216. (No model.)

Claim.—1. In a lathe for turning articles with elliptical cross-section, the combination with the slide-rest of a table 6 having a circular depression, 5, a piece 4 turning in the said circular depression a tool-holder 3 capable of sliding in the piece 4, a connecting-rod 9 and link 10 for connecting the tool-holder with the crank-pin 15 of a crank-disk 11, a slide 12 for guiding the link 10, co-acting on an adjustable journal 13, and a slotted rod 14 connecting piece 4 and the slide 12 so as to keep them parallel, this arrangement being made so as to cause the end of the tool to describe a circle the diameter of which is that described by the crank-pin, substantially as hereinbefore described and for the purpose set forth.

2. In a lathe for turning articles with elliptical cross-section, the combination with a slide-rest, of a table having a circular depression, a supporting-piece turning in the circular depression, a tool-holder adapted to slide in the said piece, a disk, a crank-pin therefor, a rod and a link for connecting the crank-pin with the tool-holder, an adjustable journal, a slide co-acting on said journal and adapted to guide said link, a slotted rod for connecting the supporting-piece and slide, gear-wheels 19, a shaft operated by the said gear-wheels, and gear-wheels 24, 25 actuated by the said shaft for operating the said crank-disk, the relative proportions of the gear-wheels 24, 25 being such that the disk turns with an angular velocity twice that of the article being turned.

3. In a lathe, a tool-holder adapted to have a tool suitably connected thereto, mechanism for reciprocating said tool-holder, mechanism for supporting and rocking said tool-holder in a circular manner simultaneously with the reciprocation thereof, operating means for the said mechanism, adjustable means for connecting the supporting and rocking mechanism to the said operating means for causing the operation of said mechanism to be changed the degree of circular movement of the said tool-holder, and adjustable means for connecting the reciprocating mechanism to the operating means for operating said mechanism and for adjusting the reciprocating movement of the tool-holder, substantially as herein shown and described.

4. In a lathe, a tool-holder adapted to have a tool suitably connected thereto, means for supporting said tool-holder to permit of the operation thereof in a circular manner, mechanism for reciprocating said tool-holder, mechanism for rocking said tool-holder in a circular manner simultaneously with the reciprocation thereof, operating means for the said tool-holder, adjustable means connected to said rocking mechanism and to said operating means for operating the former and for adjusting the reciprocating movement of the tool-holder.

701,218. ELECTRIC FURNACE. FANTO MORANI, Roma, Italy. Filed July 24, 1900. Serial No. 94,728. (No model.)

Claim.—1. In an electric furnace, an electrode, a supporting-yoke for suspending the same in said furnace and constructed to permit of the circulation of a cooling medium, a casing connected to said electrode and in communication with said yoke, means for circulating a cooling medium through said casing, and a conductor suitably connected thereto.

2. In an electric furnace, an electrode, a hollow yoke connected therewith, and a casing in contact with said electrode and in suitable communication with a source of electrical energy, said casing and yoke constructed to permit of the circulation of a cooling medium.

3. In an electric furnace, an electrode, a hollow yoke connected therewith and adapted to conduct a cooling medium, a cross-head, means for adjustably securing the yoke to the cross-head, a hollow casing extending through the cross-head and contacting with the electrode, a connection for establishing communication between the yoke and the casing to permit of the circulation of the cooling medium, and an electrical conductor connected with said casing.

4. In an electric furnace, an adjustable yoke for suspending an electrode and adapted to conduct a cooling medium, and a casing contacting with said yoke and in communication with a source of electricity, said casing communicating with said yoke to permit of the circulation thereof of said cooling medium.

5. In an electric furnace, an adjustable hollow yoke for suspending an electrode, a casing contacting with the electrode, a connection between the casing and the yoke for establishing communication between them, and a suitable connection between said casing and a source of electrical energy.

6. In an electric furnace, a hollow yoke connected to an electrode, a casing contacting with the electrode, means for establishing communication between said yoke and casing, means for supplying said yoke and casing with a cooling medium, and a suitable connection between said casing and a source of electrical energy.

701,219. APPARATUS FOR THE MANUFACTURE OF COKE.
PAUL HARR, New York, N. Y. Original application filed Sept. 7, 1901. Serial No. 690,781. Divided and this application filed May 1, 1902. Serial No. 15,092. (No model.)

Claim.—1. A coking apparatus consisting of a shaft provided at its lower end with a coke-outlet and having inlets for gaseous fluid, inlets for steam at a lower level than the gaseous-fluid inlets and inlets for water at a still lower level all of said inlets being above the coke-outlet.

2. In a coking apparatus, the combination of a shaft having an outlet for by-products at its upper end and an outlet for coke at its lower

end and means for feeding coking material downwardly through said shaft, of means for introducing heated fluid into the shaft at a considerable distance above the coke-outlet and means for injecting steam into said shaft at a point below the gas-inlets and above the coke-outlet.

3. In a coking apparatus, the combination with a shaft or stack comprising a coking-chamber provided with an outlet for by-products, and a cooling-chamber for coke below the coking-chamber having an outlet for coke at its lower end, of a hollow ring encircling the shaft or stack at the juncture of said chambers and communicating with the interior of said stack or shaft and means for introducing hot gas into said ring.

4. In a coking apparatus, the combination with a stack or shaft having an inlet for fuel and an outlet for by-products at its upper end and an outlet for coke at the lower end, said stack or shaft comprising upper and lower communicating chambers, of means for introducing hot gas at the juncture of said chambers.

5. In a coking apparatus, the combination with a stack or shaft having an inlet for fuel and an outlet for by-products at its upper end and an outlet for coke at the lower end, said stack or shaft comprising upper and lower communicating chambers, of means for introducing hot gas at the juncture of said chambers and means for introducing steam and water into the lower chamber.

6. In a coking apparatus, the combination with a stack or shaft adapted to permit the free passage of fuel from top to bottom and having an outlet at its upper end for by-products, of an outlet hopper or funnel at the lower end of said stack or shaft, adjustable doors in said hopper and crushing devices in said hopper or funnel below the doors.

7. In a coking apparatus, the combination with a shaft provided at its upper end with an outlet for by-products and means for feeding material into the shaft, and provided at its intermediate portion with a series of trays, of a separate heated combustible gas-producer and means for conveying the heated combustible gas to said series of trays, and means for discharging coke from the lower end of the shaft, substantially as set forth.

8. In a coking apparatus, the combination of a part for coking fine coal, a part for treating the coke with steam and devices for crushing the treated coke as it leaves the apparatus.

9. The combination with two shafts filled with fuel, means for conducting hot gas from the first into and through the second and sprays for introducing liquid into said hot gas.

701,220. BRAKE-BLOCK. JOHN S. COOMAS, Central City, Colo. Filed Dec. 26, 1901. Serial No. 57,816. (No model.)

Claim.—1. A brake-block comprising a shoe having a transverse ridge across its back and a bolt-hole on each side of the shoe, one above and the other below the ridge, and both lying in the plane of the shoe and in a vertical line with each other, and a supporting-bar having a horizontal groove on its face to receive the transverse ridge of the shoe and having also formed on it two slotted wings, one above and the other below the bar, and bolts passing through the slots of the wings and the vertically-aligned holes of the shoe substantially as and for the purpose described.

2. A brake-block comprising a shoe having parallel side flanges *b'* and a back portion formed with a transverse ridge with pairs of bolt-holes *b*, one pair above and the other below said ridge and both lying in the vertical plane, and a supporting-bar having an arched portion *a* fitting on the ridge and formed also with rigid slotted wings *a'*, one above and the other below the arched portion, and bolts *d* passing through the slots of the wings and the vertically-aligned holes of the brake-shoe substantially as and for the purpose described.

701,221. WEB-TREATING MACHINERY. ALBERT E. RAY, Ashland, Mass. Filed July 11, 1900. Serial No. 69,688. (No model.)

Claim.—1. In an apparatus of the class described, the combination with an impression-cylinder having peripheral web-controlling means, and a clear device, of a web-guide co-acting in contact to, and arranged closely adjacent the periphery of said cylinder, to maintain the web in

close relation with a portion thereof; said guide having a bearing to permit clearance of said web-controlling means, and being constructed and arranged to deliver said web over one of the members of said shear device to the shearing edge, at an upwardly-inclined angle, to thereby cause the web to free itself automatically from said shearing edge after each shearing operation.

2. In an apparatus of the class described, a work-guide, comprising a carrier w , having threaded portions w^1, w^2 ; bearings d^1 therefor; work-directing members W, W' , carried by said threaded portions, and guide portions w^3, w^4 , on said members.

3. In an apparatus of the class described, a shaft; and a tappet thereon; said tappet comprising an attachment mounted on said shaft, a head supported by carriers extended from said attachment, means to regulate the degree of extension of said head, and means to maintain said head in extended position.

4. The combination with a driven member having a periphery adapted to be engaged frictionally and thereby actuated, of a rotating tappet or actuating member having a frictional actuating-surface, and means to prevent engagement of said periphery by said surface until said tappet has reached a relative position insuring high frictional efficiency.

5. In an apparatus of the class described, a frame; a shaft carried thereby, and a tappet on said shaft; said tappet comprising an attachment secured to said shaft, a head carried by said attachment and movable toward and away from said shaft, and means to maintain said head in extended position; and a projection on said frame adapted to engage said head and cause retraction of the latter toward said shaft during a portion of its relative period.

6. In a machine of the class described; a rotary printing member having a groove parallel with its axis to receive and retain a chain; an elongated chain adapted to enter said groove lengthwise and engaged inferiorly to cause its retention by the walls of said groove; and a spring device carried by said rotary member and adapted to traverse the walls of said groove and engage said chain to prevent accidental lengthwise displacement thereof from said groove.

7. A printing-machine of the class described comprising printing and cutting mechanisms constructed as specified; a printing-coupler to operate upon the web and a rotating tappet having a frictionally-actuating surface to actuate the impression-cylinder of said coupler; and a work-guide intermediate said printing and cutting mechanisms; said instrumentalities co-operating upon a continuous web to produce therefrom at a high rate of speed individually perfect tickets bearing printed matter corresponding exactly in alignment on the respective tickets.

701,222. SHOW-CASE. JAMES B. HILL, Baltimore, Md. Filed Jan. 20, 1908. Serial No. 93,994. (No model.)

Claim.—1. A joint-strip for show-cases having a longitudinal corrugation forming a cushioning-spring and edge wings, and provided with a fastening-bracket secured at one end within the joint-strip to the longitudinal corrugation thereof, substantially as set forth.

2. A joint-strip for show-cases having an intermediate longitudinally-corrugated bow portion forming a cushioning-spring and provided at its inner and outer edges with the projecting wings of sufficient length to lap on opposite sides of the plate to which it is applied, substantially as set forth.

3. The combination in a show-case of the abutted and abutting-plates, the joint-strip fitting between said plates, the bracket secured to the joint-strip having a wing secured to the abutting plate, and an arm for connection with the abutted plate, said wing and arm being arranged within the show-case, and means connecting the said arm with the abutted plate, substantially as set forth.

4. A joint-strip in the form of a clamp having side wings and notched in the edge of one of said wings, and a fastening-bracket secured at one end within the strip and extending between its ends through the edge slot of the wing, substantially as set forth.

5. In a show-case, the combination of the joint-strip, for application to adjoining glass plates and having inner and outer projecting wings, to lap alongside the edge of one glass plate, and having its inner wing notched for the passage of the bracket, the bracket fitting in said notch and arranged for connection with one of the adjoining glass plates, substantially as set forth.

6. The combination of the abutted and abutting plates, the resilient joint-strip fitted to the edge of the abutting plate and between the same and the abutted plate, the connecting-bracket secured to the resilient joint-strip and having a wing extending along the inner side of the abutting plate and secured thereto, and the screw or bolt secured to the said bracket, and means operating in connection with said screw for securing the abutted plate substantially as set forth.

701,228. MACHINE FOR REMOVING GARLS FROM WHEAT. WILEY E. RICE, Manassas, Va., assignor of one-half to Irven E. Welverton, Manassas, Va. Filed Oct. 7, 1901. Serial No. 77,894. (No model.)

Claim.—1. The combination, with the rollers, the rotary brushes working against the rollers, and the scraper-bars, of the scrapers pivotedly hung adjacent to the brushes, and the spring-controlled tooth-levers secured to the scrapers and engaging said bars for operating the scrapers to vary their bearing on the brushes.

2. The combination with the rollers, and the rotary brushes, of the bearing-plates upon each of which a roller and a brush are journaled and having a slot extending from one bearing to the other of said plates to permit the adjustment of the plates so that the latter will carry with them without removal therefrom the rollers and brushes.

3. In a grain-separator, the combination, with the rollers, the rotary brushes, and the chutes, of the detachable boards reaching from the brushes into the chutes, and means for adjusting the boards relative to the brushes.

4. In a machine for separating garlic from wheat, the combination of the rollers and brushes, the plates each forming a bearing for a roller and a brush and having a slot extending from one bearing to the other for adjustment, the scraper-bars, the pivoted tooth-scrapers, having a toothed

hand-lever for operating them, a plate-spring on the lever to keep the teeth in engagement with the said bar, the clutches, the removable gear-boards reaching from the brushes to the clutches, and the dotted brackets upon which the boards are adjusted, substantially as and for the purpose set forth.

701,924. SCHOOL-BAG. HENRY C. ROBINSON, Fayetteville, W. Va. Filed June 2, 1901. Serial No. 61,702. (No model.)

Claim.—1. In a device of the character described, the combination with a back of stiff material, a metallic flange secured to the lower edge of said back, a flexible flap secured to said flange and an overlapping flap carried by the upper edge of said back for the purpose described.

2. In a device of the character described, the combination with a back of stiff material, a metallic flange secured to the lower edge of said back, a flap secured to said flange, an overlapping flap carried by the said back, a handle on the top edge of the back and cross-straps to hold the flaps in position.

701,925. APPARATUS FOR CUTTING SCREWS OR SPIRALS. HENRY G. ROBINSON, London, England. Filed May 17, 1901. Serial No. 61,771. (No model.)

Claim.—1. The combination of a slide-rest, a cutter or tool frame and a lever both pivotally mounted on the transverse slide of said slide-rest, gearing connecting said cutter or tool frame and said lever so that one cannot turn without the other, and means pivotally and adjustably connecting said lever to the longitudinal slide of the slide-rest, substantially as, and for the purpose, heretofore described.

2. The combination, in a lathe, of a slide-rest, a cutter or tool frame and a guide-frame with a slider forming a lever, both frames pivotally mounted on the transverse slide of said slide-rest, gearing connecting said cutter or tool frame and said guide-frame, an adjustable block carried by the longitudinal slide of said slide-rest, and a pivot-pin connecting said

slider and said adjustable block, substantially as, and for the purpose, heretofore described.

3. The combination, in a lathe, of a slide-rest, a cutter or tool frame and a guide-frame with a slider forming a lever both frames being pivotally mounted on the transverse slide of said slide-rest, bands connected at their ends to said cutter or tool frame and said guide-frame respectively, tangent wheels and screws for adjusting said bands, a pivot-pin on said slider, and means for connecting said pivot-pin to the longitudinal slide of the slide-rest, substantially as, and for the purpose, heretofore described.

4. The combination, in a lathe, of a slide-rest, a cutter or tool frame and a guide-frame with a slider forming a lever both frames pivotally mounted on the transverse slide of said slide-rest, gearing connecting said cutter or tool frame and said lever, brackets mounted on the longitudinal slide of said slide-rest, a T-piece having its cross-arm adjustably secured in said brackets, a block adjustably secured on the stem of said T-piece, and a pivot-pin on the slider and working in said block, substantially as heretofore described.

5. The combination, in a lathe, of a slide-rest, a bush or stem mounted in the transverse slide of said slide-rest, a cutter or tool holder rotatably mounted on the end of said bush or stem, a cutter-spindle pivotally mounted in said holder, a spindle journaled in said bush or stem, gearing connecting said cutter-spindle and the spindle in said bush or stem, gearing for driving the spindle in said bush or stem, a guide-frame pivotally mounted on said transverse slide, a slider in said guide-frame, gearing connecting said cutter or tool holder with said guide-frame, and a pivot-pin on the slider adjustably connected to the longitudinal slide of said slide-rest, substantially as, and for the purpose, specified.

6. The combination, in a lathe, of a slide-rest, a cutter or tool holder pivotally mounted on the transverse slide of said slide-rest, a hub on said holder, a sleeve pivotally mounted on said transverse slide, rings rotatably mounted on said sleeve, teeth formed on said rings, tangent-curved journaled in a bracket on said sleeve, flexible bands each connected at one end to one of said rings and at the other to the hub of said cutter or tool holder, a guide-frame mounted on said sleeve, a slider in said guide-frame and a pivot-pin on said slider and adjustably secured to the longitudinal slide of said slide-rest substantially as described.

7. The combination, in a lathe, of a slide-rest, a cutter or tool frame and a guide-frame with a slider forming a lever, both frames pivotally mounted on the transverse slide of said slide-rest, a sleeve rigidly attached to said guide-frame, a split collar encircling said sleeve and anchored to said transverse slide, a clamping-screw uniting the ends of said split collar, gearing connecting said cutter or tool frame and said sleeve, and a pivot-pin connecting said slider and the longitudinal slide of said slide-rest, substantially as, and for the purpose specified.

701,926. COMBINATION BUNG AND TAPPING-BUSH. JOHN BURN, Mansfield, Ohio. Filed Nov. 14, 1901. Serial No. 62,202. (No model.)

Claim.—1. A combination bung and tapping-bush, comprising a bung-bushing having a bore of even diameter, an outer flange thereon, the flange provided with internal bayonet-slots to which lead notches, a shoulder formed at the point of connection of the flange and bushing, an annular internal upwardly-inclined rib formed in the bore of the bushing below the shoulder whereby an annular groove is formed between the upper end of the rib and the inside of the bushing, the bushing adapted to receive a cylindrical bung, projections on the bung adapted to be received in the bayonet-slots, the bung provided with an annular groove on its reverse and a cup-shaped recess upon its obverse, the wall of the recess forming the lower wall of the groove, against receivable in the groove, a tapping-bush comprising an outer annular right-angular depending flange, projections on the outer wall of the flange, the projections adapted to be received in the bayonet-slots the right-angular flange including an inverted groove, the inner wall of the groove formed of an elongated depending member, the elongated member being hollow and extending some distance below the horizontal plane of the right-angular flange, the tapping-bush and bung being interchangeable.

2. A combination bung and tapping-bush comprising a bung-bushing, an outer flange thereon, the flange provided with internal inclined bayonet-slots having notches connected therewith, a shoulder formed at the point of connection of the flange and bushing, an annular upwardly-inclined rib formed in the bore of the bushing below the shoulder whereby an annular groove is formed between the upper end of the rib and the inner circumference of the bushing, and a tapping-bush, the tapping-bush provided with a right-angular depending flange, projections on the de-

pending wall of the flange, the projections adapted to be received in the bayonet-slot of the bushing, and a gasket received in the groove formed between the depending wall of the flange and the body portion of the tapping-bush, the body portion of the tapping-bush being extended some distance beyond the depending wall of the flange.

701,927. COAL-CHUTE. WILLIAM E. SMITH, Grand Island, Neb.
Filed Jan. 4, 1902. Serial No. 63,363. (No model.)

Claim.—1. A chute having a hinged apron at its lower end with supporting-chains on each side, and pulleys over which said chains pass, a horizontal weight having its opposite ends connected to said chains, a second horizontal weight independently supported above the first-named weight in the same vertical plane therewith, and means for guiding said weights in their vertical movements substantially as described.

2. A chute having a hinged apron at its lower end with supporting-chains on each side and pulleys over which said chains pass, a horizontal weight having its opposite ends connected to said chains, a horizontal weight independently supported above the first-named weight in the same vertical plane therewith and a vertical guide-rod passing through both of said weights substantially as described.

3. A chute having an inclined bottom and a vertical wall extending upwardly from a point near the bottom and having an opening below it the full width of the chute-bottom, vertical guideways at each side of the chute, a gate the full width of the chute arranged in said guideways and having a rigidly-attached rod projecting upwardly from the same, a chain attached to the same, a pulley located above it over which the chain passes, and a lever fulcrumed to the chute and fastened to said chain and having a pull extending to reach from below substantially as described.

4. In a railroad coal-chute, an inclined grating extending from one rail to a point below the other rail, and retaining devices at the end of said grating for holding the large lumps while being broken substantially as described.

5. In a railroad coal-chute, an inclined grating extending from one rail to a point below the other rail, a receiving-plate connected to the lower end of said grating, and a cross-bar with removable pins passing through the said cross-bar and receiving-plate to hold the large lumps while being broken substantially as described.

6. A coal-chute comprising a double inclined chute with gate and delivery devices, track stringers and rails arranged above the same, two A-shaped frames A, B, A, B, having their apices below the track-stringers and their feet brought together, and cross-braces and corner-posts substantially as shown and described.

701,928. AIR-DIFFUSER. STEPHEN C. BURR, Kansas, Mo.
Filed Nov. 25, 1901. Serial No. 59,007. (No model.)

Claim.—1. In an article of the character described, placed upon the delivery side of a fan, a series of deflecting-blades arranged concentrically one within another and means for connecting said blades.

2. In an article of the character described, placed upon the delivery side of a fan, a series of deflecting-blades arranged concentrically one within another and clamping outwardly, and means for connecting said blades.

701,928.

701,929. LABELING-MACHINE. FRANK C. E. STRANDBERG,
Chicago, Ill. Filed Jan. 31, 1902. Serial No. 63,461. (No model.)

Claim.—1. In a labeling-machine, the combination of a pair of clamping-heads to engage and rotate the receptacle while the label is being affixed thereto, a stop permanently located behind the clamping-heads and adjacent thereto, a rock-shaft beneath said permanent stop, arms mounted on said rock-shaft, a rod carried by said arms, said rod being arranged to receive and support the receptacle when it is fed to the machine and while it is resting against the permanent stop, means for lifting the rod to arrange the receptacle in labeling position between the clamping-heads, and means for lowering the rod to permit the discharge of the labeled receptacle before another receptacle is fed to the machine, substantially as described.

2. In a labeling-machine, the combination of a pair of clamping-heads to engage and rotate the receptacle while the label is being affixed thereto, a fixed stop at one side of the clamping-heads, a discharge-chute, a rock-shaft, arms mounted on said rock-shaft, a rod carried by said arms beneath the clamping-heads to receive and support the receptacle when fed to the machine, a spring device for lifting the rod to arrange the receptacle in labeling position between the clamping-heads, and means for lowering the rod after the receptacle has been engaged by the clamping-heads, so that the receptacle may drop into the discharge-chute when the clamping-heads are released, substantially as described.

3. In a labeling-machine, the combination with a pair of rotatable clamping-heads to receive and rotate the receptacle to be labeled, a main shaft, a label-supply holder, a feed-cam on the main shaft and arranged to carry a label forward from the supply, a paste-roll, a feed-roll located above the paste-roll and arranged to receive the label carried forward by the feed-cam and feed said label onto the receptacle, an affixing-roll be-

ated above the receptacle, a rock-shaft, arms on said rock-shaft and carrying said affixing-roll, and a cam on the main shaft for locking said rock-shaft, substantially as and for the purpose described.

4. In a labeling-machine, the combination of a pair of rotatable clamping-heads, device for receiving the receptacle to be labeled and arranging the same in position between said heads, means for clamping the heads upon the receptacle, means for feeding the label to the receptacle, a main shaft, a rock-shaft, arms carried by said rock-shaft, an affixing-roll carried by said arms and device connected with the main shaft for rotating the rock-shaft to bring the affixing-roll into operative engagement with the receptacle, substantially as described.

5. In a labeling-machine, the combination of means for rotating the receptacle to be labeled, a paste device, a device for feeding a label from the paste device to the receptacle to be labeled, pawl-and-ratchet mechanism on the feed and paste device, and a device for affixing the label to the receptacle while it is rotating, substantially as described.

6. In a labeling-machine, the combination of means for rotating the receptacle to be labeled, a paste-applying device, a label-supply holder, feeding device rotating at less speed than the receptacle, a device for affixing the label to the receptacle while the latter is rotating, and means for permitting the label to move more rapidly through the machine after it is engaged by the affixing device and while still engaged by the feeding device, substantially as described.

7. In a labeling-machine, the combination of means for rotating the receptacle to be labeled, a paste-applying device, a feed-roll adjacent to said paste device, a label-supply holder, a feed device moving a label from the supply to the paste device, a device for affixing the label to the receptacle while it is being rotated, and means for permitting the feed-roll and the paste-applying device to rotate more rapidly after the affixing device has engaged the label, substantially as described.

8. In a labeling-machine, the combination of means for rotating a receptacle to be labeled, a paste-roll shaft, a paste-roll having a ratchet connection with said paste-roll shaft, a feed-roll shaft, a feed-roll normally rotating at less speed than the receptacle and having a ratchet connection with said feed-roll shaft, a label-supply holder, a device for feeding the labels from the supply to said paste-roll and feed-roll, and a device for affixing the label to the receptacle, substantially as described.

9. In a labeling-machine, the combination of means for rotating the receptacle to be labeled, a paste-roll shaft, a paste-roll having a ratchet connection with said paste-roll shaft, a feed-roll shaft, a feed-roll normally rotating at less speed than the receptacle and having a ratchet connection with said feed-roll shaft, a label-supply holder having its bottom provided with a yielding section at its front end, a cam located above said yielding section for feeding the labels from the supply, and a device for affixing a label to the receptacle, substantially as described.

10. In a labeling-machine, the combination with a receptacle-clamping head, of a fixed plate, a cleave mounted on said plate, a clamping-head rotatably mounted on said cleave, and means for moving said cleave longitudinally on the plate, substantially as described.

11. In a labeling-machine, the combination with a receptacle-clamping head, of a fixed plate, a cleave mounted on said plate and provided with an angular slot, a pin on the plate projecting up through the slot, means for moving said cleave rotatably on the plate to move the cleave laterally, and a clamping-head carried by the cleave, substantially as described.

12. In a labeling-machine, a fixed plate, a cleave mounted on said plate and provided with an angular slot, a pin on the plate projecting up through the slot, a head carried by the cleave, an arm connected with the cleave, and a device for actuating said arm to move said cleave rotatably on the plate and thereby move it laterally, substantially as described.

701,280. CHANGEABLE COMBINATION KEY-LOCK. WARREN H. TAYLOR, Stamford, Conn., assignor to The Yale & Towne Manufacturing Company, Stamford, Conn. Filed Mar. 10, 1902. Serial No. 97,668. (No model.)

Claim.—1. In a changeable combination key-lock the combination with a bolt, a fence carried by the bolt, and a tumbler coacting with the fence, of a yielding device also carried by the bolt and normally engag-

ing the front edge of the fence, and means for disengaging said device from the fence when a change in the combination is to be effected.

2. In a changeable combination key-lock, the combination with a bolt, a fence carried thereby and a tumbler coacting with the fence, of a yielding device movably mounted on the bolt and normally engaging the front edge of the fence, and means for disengaging said device from the fence when a change in the combination is to be effected.

3. In a changeable combination key-lock, the combination with a bolt, a fence carried thereby, and a tumbler coacting with the fence, of a spring-pressed arm pivoted to the bolt and carrying a spline which latter normally engages the fence, and means exterior of the casing whereby the arm may be moved to disengage the spline from the fence.

4. In a changeable combination key-lock, the combination with a bolt, a fence carried thereby and a tumbler coacting with the bolt, of a spring-actuated arm pivoted to the bolt and carrying a spline normally engaging the fence, and means engaging the pivoted arm, and accessible from the outside of the casing for moving the spline out of engagement with the fence.

5. In a changeable combination key-lock the combination with a bolt, a plurality of fences movably mounted thereon, a series of tumblers, and spacing-plates between the several fences and overlapping the adjacent ends of the tumblers, of a spline carried by the bolt and common to and normally engaging all the fences, and means for disengaging the spline from the fences when a change in the combination is to be effected.

6. In a changeable combination key-lock the combination with a bolt, a movable fence carried thereby, and a tumbler coacting with the fence, of a movable spline carried by the bolt and located between the fence and a fixed stop, the parts being so arranged that the spline can be moved only when the bolt is in its unlocked position.

7. In a changeable combination key-lock, the combination with a bolt, a movable fence carried thereby and a tumbler coacting with the fence, of an arm pivoted to the bolt and carrying a spline, the said arm being located between a fixed stop and the fence so that the arm can be moved to disengage its spline from the fence only when the bolt is in an unlocked position.

701,281. CHANGEABLE COMBINATION KEY-LOCK. WARREN H. TAYLOR, Stamford, Conn., assignor to The Yale & Towne Manufacturing Company, Stamford, Conn. Filed Mar. 10, 1902. Serial No. 97,669. (No model.)

Claim.—1. In a changeable combination key-lock, the combination with a bolt, a fence carried thereby and a tumbler coacting with the fence, of a clamping-plate for the fence, a screw carrying said clamping-plate, and means carried by the bolt and engaging a stop on the casing for preventing the bolt from being thrown to its locked position when the pressure of the clamping-plate is removed from the fence.

2. In a changeable combination key-lock, the combination with a bolt, a fence carried thereby, a tumbler coacting with the fence and a stop carried by the casing, of a clamping-plate for the fence, and a screw carried by the bolt and connected to said clamping-plate and provided with a slotted head, the slot in said head resting in line with the stop on the casing when the fence is locked by the clamping-plate.

3. In a changeable combination key-lock, the combination with a bolt, a fence carried thereby, a tumbler coacting with the fence and a stop carried by the casing, of a clamping-plate for the fence, and a screw carried by the bolt and connected to said clamping-plate, the head of said screw being constructed to engage said stop and prevent the bolt from being thrown to a locked position except when the fence is clamped by the clamping-plate.

4. In a changeable combination key-lock, the combination with a bolt, a plurality of adjustable fences carried by said bolt, a tumbler coacting with each fence and spacing and friction plates between the several fences and overlapping the ends of the tumblers, of a clamping-plate engaging the outer fences, a screw carried by the bolt and engaging the clamping-plate, a casing including said parts and provided with an opening through which the head of the screw may be reached, and means carried by the bolt for preventing the latter from being thrown to its locked position when the pressure on the clamping-plate is removed from the fence.

5. In a changeable combination key-lock, the combination with a lock, a loose screw liberty and a tumbler consisting with the flange, of a clamp for holding the flange against accidental movement, a device for adjusting said clamp, and means actuated by the clamp-adjusting device for preventing the bolt from being thrown to its locked position when the pressure of the clamp is removed from the flange.

701,282. DRAWER GUARD OR SUPPORT. MARION C. TIER.
The Dalles, Oreg. Filed Nov. 22, 1901. Serial No. 58,285. (No model.)

Claim.—1. A guide and stop for drawers comprising a strand of wire bent intermediate its ends to form two parallel arms, then on the free end of said arms and adapted to engage the drawer-support and a head in the other ends of the arms which is adapted to limit the outward movement of the drawer.

2. In a drawer guide and stop, the combination with a support, and a sliding drawer secured thereto, of a pair of parallel arms secured to the support and extending through the drawer, the free ends of said arms being bent at right angles to the arms proper, whereby said ends are adapted to engage the drawer to limit the outward movement thereof.

701,288. WHEEL ATTACHMENT FOR PLOWS. DANIEL E. TRIPP, Coldwater, Mich., assignor of one-half to John H. Neat, Coldwater, Mich. Filed Jan. 26, 1902. Serial No. 91,735. (No model.)

Claim.—A wheel attachment for plows, comprising a cross-bar having a fixed standard at one end, means to detachably and adjustably connect the cross-bar to a plow-beam, a wheel, a bearing-rod therefor, attached to and vertically adjustable on the fixed standard, and stay-rods attached to the cross-bar and adapted to be attached to the plow at points in advance and rear of the cross-bar, said stay-rods including means for lengthening and shortening them, substantially as described.

701,284. CHURN-COVER. THOMAS E. VAN HORN, Orem, Utah. Filed Aug. 17, 1901. Serial No. 72,267. (No model.)

Claim.—1. The churn-top herein described comprising the bottom case, the outwardly-projecting flange at the lower end of the tapered sides, the depending flange at the outer edge of said first flange, the bottom extending across the base of the cover forming the dead-air space, the tubular guide for the dash-rod extending between the center of the bottom and the apex of the cover, and the depending flange located

within and spaced apart from the inner depending flange forming an annular chamber to fit upon the upper end of a churn-body, said inner depending flange being provided at its upper edge with a rim-flange secured to the bottom of the cover and the clasp carried by the cover whereby to secure said cover in place upon a churn-body, substantially as set forth.

2. The churn-cover herein described comprising the base-plate provided at its outer edge with a depending flange overlapping the outer side of the churn-body, the flange depending from the base-plate and located within and spaced apart from the outer flange and arranged to lap within the churn-body, the central tubular guide secured to the base-plate and projecting upwardly from the base-plate and opening at its lower end through said base-plate, and the rigid hollow cone secured at its upper or base end to the base-plate and at its upper end to the tubular guide and forming, with the base-plate, an air-space surrounding the tubular guide substantially as set forth.

701,285. AUTOMATIC VALVED HAMMER. DANIEL E. WARD, Chicago, Ill. Filed Nov. 24, 1901. Serial No. 31,201. (No model.)

Claim.—1. In a fluid-operated hammer, the combination with a casing, a hammer movable therein, means for effecting the supply and exhaust of a motive fluid to and from the casing, and means for reducing the area of the surface of said hammer exposed to the motive fluid at one limit of movement of the hammer, of means formed in the casing for relieving the compression opposed to the hammer during the final portion of its return movement said means being supplemental to the normal exhaust.

2. In a fluid-operated hammer, the combination with a casing provided with a cushioning-plug extended therein, of a chambered hammer disposed to move within the casing and to receive the cushioning-plug, means for effecting the supply and exhaust of the motive fluid to and from the casing to operate the hammer, and means separate from the normal exhaust for relieving the compression opposed to the return of the hammer.

3. In a fluid-operated hammer, the combination with a casing provided with an inwardly-projecting cushioning-plug, of a chambered hammer mounted for reciprocation within the casing and designed to receive the plug, means for effecting the supply and exhaust of the motive fluid to and from the casing to operate the hammer, and a relief-port piercing the casing at a point above the inner end of the cushioning-plug and also opening into the casing at a point below or beyond the hammer when the latter is engaged with the plug.

4. In a fluid-operated hammer, the combination with a casing provided with principal ports opening into the opposite ends of the casing, a controlling-valve controlling the supply and exhaust through said principal ports, auxiliary ports opening into the casing and disposed to admit fluid to the controlling-valve, and means controlling the passage of fluid through said auxiliary ports, said means being controlled by the fluid-pressure within the principal ports.

5. A fluid-operated hammer comprising a casing, a valve-chest, a pair of principal ports leading from the valve-chest to the interior of the casing, auxiliary ports leading from the casing to the opposite ends of the

valve-chest, a controlling-valve within the valve-chest, automatically-operated auxiliary valves controlling the auxiliary ports, and a hammer mounted for reciprocation within the casing.

6. A fluid-operated hammer comprising a casing, a valve-chest, a pair of principal ports, and a pair of auxiliary ports, all of said ports opening into the casing and valve-chest respectively, a controlling-valve within the valve-chest, auxiliary valves controlling the auxiliary ports, means for supplying pressure from the principal ports to operate the auxiliary valves, and a hammer mounted for reciprocation within the casing.

7. In a fluid-operated hammer, the combination with a casing provided with a valve-chest and valve, a pair of principal ports communicating with the opposite ends of the casing and with a pair of auxiliary ports also communicating with the interior of the casing, all of said ports being in communication with the valve-chest, a piston-valve within the valve-chest controlling the supply and exhaust of the motive fluid to and from the ports, auxiliary-valve chambers intersecting the auxiliary ports and in communication with the principal ports, spring-pressed valves within said valve-chambers, a hammer mounted for reciprocation within the casing, and means for supplying and exhausting the motive fluid to and from the valve-chest.

8. In a fluid-operated hammer, the combination with a casing, a valve-chest disposed at one end thereof, supply and exhaust chambers disposed upon the exterior of the valve-chest and communicating therewith, principal and auxiliary ports communicating with the interior of the casing and with the valve-chest, automatically-operated valves controlling the several ports, a hammer mounted for reciprocation within the casing, a supply-port communicating with the supply-chamber, said port being intersected by an initial valve-chamber having a tapering valve-seat, an initial valve opposed to said seat, a trigger disposed beyond the casing and in operative relation with the initial valve, and a handle connected to the casing and disposed in convenient relation to the trigger.

9. In a fluid-operated hammer, the combination with a casing, a valve-chest disposed at one end thereof, a valve within the valve-chest, and a hammer within the casing, of a head closing the valve-chest and provided with a supply-port intersected by a valve-chamber having a tapered seat, a valve opposed to the seat and provided with an extended stem, a pivoted trigger mounted upon the head and provided with an operating arm and disposed at one side of said head, and a handle extended from the head at the side adjacent to the operating end of the trigger and extended over the trigger to protect the same.

701,986. MEMORANDUM AND INDICATING DEVICE. CHARLES D. WEAVER, McPherson, Kans., assignor to the McPherson Office Machinery Company, McPherson, Kans. Filed Mar. 14, 1901. Serial No. 61,000. (No model.)

Claim.—1. In a memorandum and indicating device, the combination with a cabinet or case, of a lid slidably mounted thereon, a cogged rack rigidly attached to the lid, a message-strip-operating roll, a gear loose on said roll, a connection between the gear and the roll whereby as the lid is moved in one direction the roll is actuated, and when the lid is moved in the opposite direction the roll remains idle, an indicating device, and means operated by the gear for actuating the indicating device when the lid is moved in the direction opposite that which actuates the message-strip-operating roll, substantially as described.

2. The combination with a case, of a lid slidably mounted thereon, a supply-roll located by the case, a main strip-operating roll, a tension-roll co-operating with the main roll, a gear-wheel loose on the spindle of the main roll, a dog carried by said gear, a ratchet-wheel fixed on the spindle of the main roll and arranged to be engaged by the dog carried by the gear, a cogged rack rigidly connected with the lid and engaging the gear, whereby as the lid is moved in one direction the strip-operating roll is actuated, means for locking the strip-operating roll from movement when the lid is moved in the opposite direction, an indicator, and means actuated by the gear for operating the indicator while the roll remains idle, substantially as described.

701,987. PIPE-WRENCH. GEORGE J. WENZ, Toledo, Ohio, assignor of one-half to the Ames Buckner Rod Company, Toledo, Ohio. Filed Nov. 13, 1901. Serial No. 52,008. (No model.)

Claim.—1. In a pipe-wrench, a forked handle, a pair of wrench-jaws pivotally connected together at their inner ends, a pivotal connection between one of the forks and one of the jaws, and a sliding connection between the other fork and the other jaw.

2. In a pipe-wrench, a forked handle, a pair of wrench-jaws pivotally connected together at their inner ends, a pivotal connection between one of the forks and one of the jaws, a sliding connection between the other fork and the other jaw, and a removable tooth in the gripping-face of one of the jaws.

701,988. SAFE-FASTENER. ROBERT WILLIAMS, Melbourne, South Australia, Australia, assignor to Fresh Air and Safety Safe Fastener Company, Limited, Adelaide, South Australia, Australia, a Corporation of South Australia. Filed Feb. 26, 1902. Serial No. 94,148. (No model.)

Claim.—In a safe-fastener, a stud, a plate secured thereto having a beveled stud projecting therefrom and provided with inclined surfaces, a knob rotatably and slidably mounted on said stud and carrying a spring-controlled pin passing through the bore of said stud, said knob having inclined surfaces, adapted to engage and work on those of the stud, and said inclined surfaces being respectively provided at their highest and lowest points, with engaging means for holding the pin in a retracted position against the resistance of its spring.

701,989. MEANS FOR WORKING CREEPS BY THE CYANIDE PROCESS. FRANK R. WOOD, San Francisco, Cal. Filed Aug. 13, 1901. Serial No. 71,012. (No model.)

Claim.—1. An apparatus for working creeps consisting of a plurality of tanks arranged in line, a conveyor passing through each of said tanks and returning thereunder, said conveyor elevated at the rear of the machine more than at the front, said the rear end of one of the conveyors discharging upon the front end of the other conveyor, and means whereby the conveyors may be driven in unison.

2. An apparatus for working over comprising a plurality of tanks arranged in line, each of said tanks having a conveyor passing through and returning beneath the tank, means for driving the conveyors in unison, and conveyor rollers within the tank and upon which the conveyors travel whereby the latter are given an undulatory movement while passing through the tank.

3. In an apparatus for treating ore, a containing-tank, an endless transversely-convexed belt conveyor upon which the ore is carried through the solution in said tank, and means by which an undulatory movement is given to said conveyor.

4. In an apparatus for treating ore, a containing-tank, an endless belt conveyor passing through and returning beneath said tank, means supporting one end of the conveyor at a higher elevation than the opposite end, and rollers within the tank over which the conveyor passes whereby the latter is given an undulatory movement.

5. In an apparatus for treating ore, a containing-tank, an endless belt conveyor passing through and returning beneath said tank, conveyor rollers upon which said conveyor is sustained and rods supporting the edges of said conveyor whereby the latter is kept distended.

6. In an apparatus for treating ore, the combination of a containing-tank, an endless belt conveyor, conveyor rollers on which said conveyor is supported, certain of said rollers disposed in the tank so that the conveyor passes over them in undulatory movement during its travel through the solution in the tank, and supports for said conveyor at opposite ends thereof, one of said supports being at a higher elevation than the other.

7. An apparatus for treating ore consisting in combination of a plurality of aligned containing-tanks, a transversely-convexed, endless belt passing through and returning beneath each of said tanks, and upon which the ore is carried, each of said belts discharging its load upon the belt of the next succeeding tank, means for driving said belts in unison, means by which said belts are kept transversely distended and rollers disposed at intervals in said troughs and over which the belts pass, whereby the latter are given an undulatory movement.

701,240. FEEDER FOR GRAIN-SEPARATORS. FRANK J. WOOD, Des Moines, Iowa, assignor to Wood Bros. Steel Belt Feeder Co., Incorporated, Des Moines, Iowa. Filed June 4, 1901. Serial No. 68,166. (No model.)

Claim.—1. In a feeder for the purpose set forth, a carrier-frame made up of two sections which are hinged to each other the hinges having abutting edges above their plates, a supporting-frame therefor in which one section of the carrier-frame is pivoted, rods permanently attached to be in swinging engagement with extensions of the supporting-frame and with the outer section of the carrier-frame, the points of connection being on different horizontal planes whereby the sections will be maintained in line without other supporting means, and when the hinged joint between the sections is broken upwardly the outer section will swing under the frame of the feeder and be maintained by the rods below its lower section which is pivoted to the frame.

2. In a head-cutter and feeder, the combination with a shaft, of a plurality of blades mounted on the shaft at right angles thereto each blade having a cutting edge, curvatures in each blade at those parts thereof which are furthest from the shaft, the curvatures being at one angle near the points of the blades and at an opposing angle beyond the first curvature but continuous therewith to provide curvatures on both the first to contact with the sheaves being connected in the direction of the rotation of the blades and the other curvature in a reverse direction thereto, substantially as shown.

3. In a feeder for separating, spreading-form consisting of bars having at one end depending flaps, clamps for adjustably attaching the bars to a crank-shaft, slides mounted on the bar, a ball end having bent ends

which engage the slides, and a lever rigidly attached to the ball for adjusting the same to vary the position of the slides on the bars of the flaps, substantially as shown.

4. A governor for head-cutter and feeders comprising a flanged disk, a frame separate therefrom and rigidly attached to a shaft upon which the disk is loosely mounted so that the frame will be within the flange of said disk, three similar projections on each side of the frame, bars guided by two of the projecting portions, heads on the ends of each bar, weighted arms pivoted to the other projecting portion of the frame so that when said arms are swung outward by centrifugal force the heads of the bars will be thrown into engagement with the flange of the disk, springs which unseat the bars and said springs acting to move the bars and weighted arms inwardly, units mounted on the bars with which the springs engage, and a sprocket-wheel in positive engagement with the flanged disk and loosely mounted on the shaft, substantially as shown.

701,241. HEATING APPARATUS. JOHN H. FOUNT, Alhambra, Cal. Filed Mar. 12, 1902. Serial No. 97,917. (No model.)

Claim.—1. In combination a receptacle for the storage of fuel to be used, a stove or other object or objects to be heated, connecting pipe or pipes with valves, and a receptacle containing porous, incandescent substance or substances, a raised cover or upper part above and resting upon said receptacle with openings therein for the inlet of air, and having an exit-opening at its top, and a flange around the exit-opening, a raised cap or shoulder piece sustained by legs and held in position by a closely-fitting ring around the flange at the top of said raised cover, all in proper heating relation to the stove or other object or objects to be heated, and all substantially as described and set forth.

2. In combination a receptacle for the storage of fuel to be used, a stove or other object or objects to be heated, connecting pipe or pipes with valves, a receptacle, a tube open at its upper end and forming and being a continuous piece with the bottom of the receptacle and surrounding an opening through which the fuel enters, and said tube and receptacle containing porous, incandescent substance or substances, a wire-net cover placed over said substance at or near the top of said tube, a wire-net covering the said opening into the bottom of said tube, and said receptacle having a second opening for the influx of fuel into said last-mentioned opening, a raised cover or upper part above and resting upon said receptacle with openings therein for the inlet of air, and having an exit-opening at its top, and a flange around the exit-opening, a raised cap or shoulder piece sustained by legs and held in position by a closely-fitting ring around the flange at the top of said raised cover, all in proper heating relation to the stove or other object or objects to be heated, and all substantially as described and set forth.

3. In a burner, the combination of a receptacle for the storage of fuel to be used, a stove or other object or objects to be heated, connecting pipe or pipes with valves, a receptacle, a tube open at its upper end and forming and being a continuous piece with the bottom of the receptacle and surrounding an opening through which the fuel enters, and said tube and receptacle containing porous, incandescent substance or substances, a wire-net cover placed over said substance at or near the top of said tube, a wire-net covering the said opening into the bottom of said tube, and said receptacle having a second opening for the influx of fuel into said last-mentioned opening, a raised cover or upper part surrounding said tube having openings for the inlet of air, an exit-opening at the top surrounded with a flange, its lower edges curved and a nut-screw near its lower end, all placed in proper heating relation to the stove or other object to be heated, substantially as described and for the use and purpose set forth.

4. In a burner, the combination of a receptacle for the storage of fuel to be used, a stove or other object or objects to be heated, connecting pipe or pipes with valves, a receptacle, a tube open at its upper end and forming and being a continuous piece with the bottom of the receptacle and surrounding an opening through which the fuel enters, and said tube and receptacle containing porous, incandescent substance or substances, a wire-net cover placed over said substance at or near the top of said tube, a wire-net-covering the said opening into the bottom of said tube,

and said receptacle having a second opening for the influx of fuel into said receptacle outside of said tube, a wire-net cover being placed over said last-mentioned opening, a raised cover or upper part surrounding said tube having openings for the inlet of air, an exit-opening at the top surrounded with a flange, its lower edges curved and a nut-screw near its lower end, a raised cap or shoulder piece sustained by legs and held in position by a closely-fitting ring around the flange at the top of said raised cover, all placed in proper heating relation to the stove or other object to be heated, substantially as described and for the use and purpose set forth.

5. In a burner, the combination of a receptacle for the storage of fuel to be used, a stove or other object or objects to be heated, connecting pipe or pipes with valves, the receptacle containing with the raised cover or upper part for the inlet of air, an exit-opening at its top with a flange surrounding said exit-opening, a raised cap or shoulder piece sustained by legs and held in position by a closely-fitting ring around the flange at the top of said raised cover or upper part, said receptacle having its lower end or bottom closed except an opening in the bottom for the influx of the fuel from the said connecting-pipe, all in proper heating relation to the stove or other object or objects to be heated, and all substantially as described and set forth.

701,242. SCREW-PROPELLER. JAMES ARNHEIM, San Francisco, Cal. Filed Sept. 4, 1900. Serial No. 20,000. (No model.)

Claim.—1. A propeller-blade consisting of conical flange having uniform shape mounted diagonally upon suitable hub and projecting at its ends downwardly beyond the center of the hub, substantially as set forth and for the purpose specified.

2. A propeller composed of two blades mounted upon a suitable base and diagonally thereof, said blades being so constructed as to provide the openings substantially around the hub, for the purpose specified.

3. A reversible propeller composed of two conical blades provided with bases mounted upon suitable hub, and having their ends formed substantially alike and provided with inward curves at each end of the base thereof, as set forth and for the purpose specified.

4. In a propeller having conical blades provided with suitable bases mounted diagonally upon the hub, inward curves formed substantially alike at the center of the blades near the hub, as set forth and for the purpose specified.

5. A propeller composed of two blades provided with suitable bases mounted upon the hub, having downwardly-projecting ends formed substantially alike and inward curves made between the center of the projecting ends of the blades and the hub, as set forth and for the purpose specified.

6. In a reversible propeller, conical blades having narrow channels or bases mounted diagonally upon suitable hub and projecting at their ends downwardly toward the center of the hub at its ends and inward curves formed at the center of the blades offsetting the base portion, substantially as set forth and for the purpose specified.

7. In a reversible propeller, blades consisting of conical flanges of uniform shape, having suitable bases mounted diagonally upon suitable hub, and projecting downwardly at their ends beyond the ends of the hub, inward curves formed substantially alike between the center of the extreme ends of the flanges and the hub, as set forth and for the purpose specified.

8. A propeller composed of a hub, two blades mounted thereon and having downwardly-projecting ends, as set forth and for the purpose specified, substantially around the hub for the purpose specified.

701,243. STAMP-SUPPORTING MACHINE. JOHN F. ARNHEIM, San Francisco, Cal. Filed July 17, 1901. Serial No. 20,000. (No model.)

Claim.—1. In a stamp-officing machine, the combination with a stamp and a stamp-supporting table; and a housing secured to the table

above the said and having upwardly-extending sheet-plates on the upper portion thereof, of a plunger within the housing operating in connection with the said, a toothed stem connected with the plunger and projecting upwardly between the said sheet-plates, a spring for driving the plunger downward, a transverse driving-shaft journaled in the said sheet-plates, a mated gear on said shaft and meshing with the plunger-stem teeth, a stamp-feeding mechanism, and operative connection between the mated gear and feeding mechanism whereby the feeding mechanism is checked simultaneously with the tripping of the plunger.

2. In a stamp-officing machine, the combination with a stamp-supporting table having a plunger-housing secured thereon, of a reciprocating plunger positioned in said housing, means for operating the said plunger; of a feeder-shaft geared to the operating mechanism and extending transversely of the table, and a series of toothed feeder-wheels mounted on said shaft and spaced apart so that the teeth on the wheels will enter the perforations in the sheet of stamps.

701,244. COLLAR OR GUFF BUTTOL. JOHN F. ARNHEIM, San Francisco, Cal., assignor, by direct and mesne assignments, to John T. Clark and John G. Martin, Bay Ridge, Mich. Filed Sept. 7, 1900. Serial No. 20,312. (No model.)

Claim.—1. In a button, the combination with the base and a post rising therefrom, of a longitudinal passage extending through said post from end to end and open at both ends, an endwise-movable spindle located in said passage and having its lower end exposed at the outer side of the base, a head secured to the upper end of said spindle, and a spring engaging the spindle and tending to force it out of the passage at the lower end thereof, substantially as described.

2. In a button, the combination with the base and a post rising therefrom, said post having through it a longitudinal passage open at both ends, of an endwise-movable spindle located in said passage and having at its lower end an enlarged head exposed at the outer side of the base, a head secured to the other end of said spindle and adapted to rest upon the upper end of the post, and a spring-surrounding the spindle and bearing in one direction against the post and in the other direction against the enlarged head of the spindle, substantially as described.

701,345. PEDAL-BALANCE. FRANK R. ANDERSON, Walpole, N. H. Filed Apr. 8, 1901. Serial No. 34,093. (No model.)

Claim.—1. A pedal-balance substantially as shown and described comprising the supporting-rod, means for connecting them with the pedal, the weight-carrying rods extending at right angles to and across the supporting-rod and having deflected portions fitting between said supporting-rod, the cross panels through the space between the supporting and carrier rods, the nut and washers for securing the carrier-rods and supporting-rods together, and the weights on the carrier-rods on opposite sides of the supporting-rods substantially as set forth.

2. A pedal-balance substantially as described comprising the parallel supporting-rods, the parallel weight-carrying rods crossing the supporting-rods at a right angle, the weights on the carrying-rods, means for securing the carrying-rods to the supporting-rods and means for securing the supporting-rods to the pedal-frame substantially as set forth.

3. The combination of the parallel supporting-rods spaced apart, the parallel carrier-rods crossing the supporting-rods and having depressed portions between the supporting-rods, the weights on the carrier-rods, and the connecting devices for securing the carrier-rods to the supporting-rods substantially as set forth.

4. The combination with the front and rear plates of the pedal, of the supporting-rods formed from a length of wire bent upon itself and having its bent and upturned forming wings lapped alongside and secured to the front plate of the pedal, the rear ends of the arms or rods being upturned forming wings secured to the rear plate of the pedal, the weight-carrying rods secured between their ends to the supporting-rods and the weights on the carrying-rods on opposite sides of the supporting-rods substantially as set forth.

5. The combination of the supporting-rods, the carrier-rods crossing the same at right angles and adjustable along the supporting-rods, and the weights having openings to receive the ends of the carrier-rods and carried thereby on opposite sides of the supporting-rods substantially as set forth.

701,346. INSULATOR PIN AND BRACKET. HENRY T. RABY, Mount Kisco, N. Y. Filed Mar. 28, 1902. Serial No. 34,093. (No model.)

Claim.—1. An insulator-pin consisting of two members formed of yielding material normally spaced apart to be forced toward each other by the application of an insulator and having at their upper ends means for securing an insulator thereon, and at its lower ends means for securing the same to a support.

2. An insulator pin or bracket comprising two independent members having yielding portions and normally spaced apart means at the ends of the members for securing an insulator thereon, the lower ends of said members being projected outwardly and fashioned to embrace and be secured to a suitable support, substantially as described.

3. The combination with a support, of an insulator-pin embracing the support and having complementary portions spaced apart, threads on the outer ends of the members, and an insulator secured on the threaded portions and serving to draw the members toward each other, substantially as described.

4. An insulator-pin comprising two independent members, with means for securing the members independently to a support, threaded extensions on the members, and an insulator on the threaded extensions normally tending to draw the members toward each other, substantially as described.

5. An insulator-pin comprising two independent spring members having their insulator-supporting ends arranged in proximity to each other but out of contact, and provided with threads for receiving and securing an insulator in place, substantially as described.

6. An insulator-pin comprising two members fashioned to embrace a support, and having insulator-carrying portions arranged so that upon the application of the insulator the members will be secured to the support, substantially as described.

7. In an insulator-pin, the combination with an insulator, of a pin

comprising two members fashioned to be forced into contact with the holding-support by the application of the insulator, substantially as described.

8. The combination with a threaded supporting-arm, of an insulator-pin having portions bent and engaging in the channel of the supporting-arm, and means on the pin for supporting and carrying an insulator, substantially as described.

9. In an insulator-pin, the combination with two metallic members, of threaded blocks secured to the outer face of the members, and means for securing the members to a suitable support, substantially as described.

10. An insulator-pin comprising two yielding members normally spaced apart, and insulating-blocks secured to the members on the outer faces thereof, and with which the insulator is adapted to engage, substantially as described.

11. A metallic insulator-pin comprising two members arranged in opposite relation, having outwardly-projecting lower portions fashioned to engage a suitable support, and inclined upper ends having projections for engaging and holding an insulator, substantially as described.

12. The combination with a supporting-arm, of two pin-sections arranged to embrace the arm and having inclined upper portions normally spaced apart, and means on the upper portions for engaging and securing an insulator thereon, substantially as described.

13. The combination with a supporting-arm, of an insulator-pin comprising two metallic members fashioned to engage a support, having their upper ends inclined and provided with suitable threaded portions, means for the inclined portions, and a block interposed between the threaded portions, substantially as described.

14. The combination with a supporting-arm, of an insulator-pin comprising two metallic members fashioned to engage a support, having their upper ends inclined and provided with suitable threaded portions, and a block interposed between the threaded portions, substantially as described.

15. The combination with an insulator-pin, of projections thereon, and independent insulating-blocks on opposite sides of the pin held in place by the projections, substantially as described.

16. An insulator-pin comprising separated portions and having means for securing an insulator thereon, of an insulating-fiber between the said portions, substantially as described.

701,347. TROLLEY. WILLIAM L. RAKER, Fairport, Ohio. Filed Jan. 20, 1902. Serial No. 34,092. (No model.)

Claim.—1. In a trolley device, the combination with a bowed frame or harp having terminal supporting parts spaced substantially parallel with the wire, of a trolley-wheel having therein to have free angular adjustment with respect to the frame, and springs adapted to maintain the electrical continuity of the said parts and assist the wheel to its normal position, substantially as set forth.

2. In a trolley device, the combination with a frame or harp bowed or expanded at *c*, said frame having terminal parts *a* providing supporting slides or ways lying substantially in a horizontal plane when the device engages the trolley-wire, of a trolley-wheel mounted therebetween and permitted free angular adjustment within the horizontal supporting-ways, and contact-springs *b* engaging said trolley-wheel and frame, substantially as set forth.

3. In a trolley device, the combination with a bifurcated frame or harp having spaced supporting or terminal parts, the distal ends of the arms of a length of least equal to the horizontal width of the sign-body, the lower bracket-arm being provided with an upstanding plate, and the upper bracket-arm being provided with a bearing-rod aligned with the

the distal, wherein it is freely movable to permit of the angular adjustment of the wheel within its frame, and lateral springs *b* engaging the wheel and frame adapted to maintain the electrical continuity between said parts, and return the wheel to its normal position, substantially as set forth.

701,348. REMOTE ALARM FOR CLOTH-FINISHING MACHINERY. JOHN F. RABBY, Central Falls, R. I. Filed Aug. 4, 1901. Serial No. 71,421. (No model.)

Claim.—1. In a cloth-finishing machine having one or more bowls made of non-conductor material, the combination, of a crank adapted to extend longitudinally with one of said bowls, said crank comprising a metallic supporting-bar, two rubber strips secured upon said bar, one of said strips provided with a series of grooves extending through at an angle from either edge thereof, a series of thin metallic blades secured within the grooves of said strip and projecting outwardly therefrom, a wire having its ends attached to each alternate blade of said crank as to form multiple having positive and negative pole connections, as shown, a battery having one pole wired to one of the pole connections, and its other pole wired to said alarm and thence to the other pole connection, substantially as shown and described.

2. In a cloth-finishing machine having one or more bowls made of non-conductor material, the combination, of a crank adapted to extend between the end frames of the machine, two strips made of non-conductor material secured upon said bar, a series of metallic blades secured between said strips and projecting at an angle therefrom, a wire connected to each alternate blade, a battery, a wire from said battery to a positive pole of said blades, an alarm actuated by said battery, a wire from said alarm to a negative pole of said blades, with brackets secured to the end frames of the machine adapted to support the blades and provided with means of adjustment to extend the projecting ends of the blades upon the periphery of the bowl, substantially as shown and described.

3. In a cloth-finishing machine having one or more bowls made of non-conductor material, the combination, of a crank provided with a series of blades, a wire connecting each alternate blade of said crank, a battery wired to one of said blades, an alarm actuated by said battery and wired to the next adjoining blade, each of said blades projecting at an angle to the plane of rotation of the bowl, so arranged that a piece of metal caught in the surface of the bowl will make a positive and negative pole connection upon the blades, as set forth.

701,349. ADVERTISING DEVICE. HENRY L. RAKER, Cincinnati, Ohio, assignor, by mesne assignments, to Mack and Beach Company, Cincinnati, Ohio. Filed Aug. 25, 1900. Serial No. 28,693. (No model.)

Claim.—1. In a sign, the combination with a rotatable body having its opposite sides capable of receiving advertising matter, opposite supporting-brackets having laterally-projected arms of a length at least equal to that radius of the sign-body which is parallel with the arms, one of the bracket-arms being provided with a plate projected toward the other arm, and said other arm being provided with a bearing-rod aligned with the plate, a bearing-socket rigidly secured to one edge portion of the sign-body and rotatably embracing the plate, and a plate carried by the diametrically opposite edge portion of the sign and rotatably fitting the bearing-rod of said other bracket-arm, whereby the sign-body is capable of a complete rotation between the brackets.

2. In a sign, the combination with an upstanding sign-body, of a rotatable body having advertising matter upon the opposite faces thereof, of upper and lower supporting-brackets having laterally-projected arms of a length of least equal to the horizontal width of the sign-body, the lower bracket-arm being provided with an upstanding plate, and the upper bracket-arm being provided with a bearing-rod aligned with the

plate, a bearing-socket rigidly secured in the lower edge portion only of the sign-body and rotatably embracing the plate to form a stop-bearing, and a plate located diametrically opposite the bearing-socket and rotatably fitting the bearing-rod of the upper bracket-arm, whereby the sign-body is capable of a complete rotation between the brackets.

701,350. DISPLAY DEVICE OR EXHIBITOR. DAVID T. BULL, Norfolk, Va., assignor of one-half to Richard D. Dandridge, Norfolk, Va. Filed Dec. 8, 1900. Serial No. 28,694. (No model.)

Claim.—1. In a pattern-exhibitor, the pattern-band, the feed and take-up rollers therefor, the electric motor having a driving connection with said band, the rotary switch, the switch-pulley in gear with the shaft of said switch, the slidable tongue, cord or the like oppositely wound upon said pulley and connected to said tongue, and means carried by said band for operating said tongue to rotate said pulley and switch, substantially as specified.

2. In a pattern-exhibitor, the pattern-band, the feed and take-up rollers for said band, the electric motor having a driving connection with said rollers, the terminal air-cylinders, the pistons in said cylinders in contact with the motor-terminals and arranged to fill at different rates of speed, and normally in electrical connection, means operated by the band for raising and releasing said pistons to break the electrical connection therebetween, substantially as specified.

3. In a pattern-exhibitor, the pattern-band, the feed and take-up rollers for said band, the electric motor having a driving connection with said rollers, and means for intermittently and automatically making and breaking the circuit of said motor, having the terminal cylinders normally electrically connected, the pistons and piston-rods of said cylinders, means for intermittently raising and releasing said pistons and rods, and means whereby said pistons and rods fill at different rates of speed to temporarily break such electrical connection therefrom, and for again making such electrical connection upon the termination of each fill, substantially as specified.

4. In a pattern-exhibitor, the pattern-band, the feed and take-up rollers therefor, the electric motor having a driving connection with said rollers, and a gravity make-and-break device in circuit with said motor, and consisting of the terminal air-cylinders, their pistons and hollow piston-rods, a pawl operated by the band for raising said pistons and rods, the inclined guide for said pawl, said rods having engaging flanges, substantially as specified.

701,351. WRAPPING-MACHINE. JOHN F. RABBY, Chicago, Ill., assignor to the Harvester King Company, Harvey, Ill., a Corporation of Illinois. Filed Jan. 1, 1902. Serial No. 71,422. (No model.)

Claim.—In a reaping-machine, the combination with the main frame of a reach connected to the forward edge of the main frame by a horizontal pivot, a ground-wheel connected to the forward end of the reach by a vertically-arranged stem mounted to turn in suitable bearings and having flanges embracing the ground-wheel, and a draft-tongue pivoted to said flanges by horizontal pivots, substantially as described.

701,252. GARMENT. HENRY SANDLER, Philadelphia, Pa., assignor to Morris Liveright, Philadelphia, Pa. Filed Oct. 11, 1901. Serial No. 73,331. (No model.)

Claim.—1. A garment having a divided waistband, a pocket having its rear wall divided from the adjacent portion of the garment below one wall of said band, a gusset occupying the space between the divisions, and a fastening having its members on the opposite walls of said band, said gusset being secured at one side to one wall of said band and a portion of the garment below the same, and at the other side to the opposite wall of said band and the rear wall of the pocket below the same.

2. A garment having a pocket and a gusset, said garment being vertically divided along the line of said pocket, said gusset occupying the space between the division of the garment, one side of said gusset being secured to one wall of the division and the other side being partly secured to the opposite wall of the division and the rear wall of said pocket.

701,253. BATTERY. GEORGE S. BARNETT, San Francisco, Cal., assignor to Joseph W. Thatcher, San Francisco, Cal. Filed Aug. 6, 1901. Serial No. 71,120. (No model.)

Claim.—1. A battery comprising in combination, a casing, a cap

thereof, a voltaic pile, a sleeve secured in the cap and forming one terminal of the battery, a conducting and supporting rod for the pile, forming the opposite terminal of the battery, said rod extending through but insulated from the sleeve and serving to firmly connect the battery elements to the cap.

2. A battery comprising a voltaic pile, a casing including the same, a cap or cover arranged at the upper end of the casing and to which the voltaic pile is secured, terminal connections carried by said cap or cover, a socket member removable from the cap and having terminal contacts connected to the line-wires, said contacts being adapted to make contact with the terminal connections of the cap or cover when the socket member is in place.

3. The combination in a battery, of a casing, a cap therefor screwing into the casing, a voltaic pile secured to and carried by the cap, a sleeve carried by the cap and forming a terminal connection from the uppermost of the battery elements, a conductor-rod passing through the sleeve and insulated therefrom and forming a terminal connection from the lowermost of the battery elements, and a socket member connected to one of the line-wires and adapted to said sleeve, and an inner contact carried by and insulated from the socket member and connected to the opposite line-wire, substantially as specified.

4. The combination in a battery, of a casing, a central rod of conducting material, a series of disks of positive and negative elements supported on said rod and insulated therefrom, said central rod being in electrical contact with the lowermost element, a casing cap or cover of non-conducting material through which the central rod passes, a sleeve of conducting material passing through the cap and having a lower flange in contact with the uppermost element, and means for attaching the line-wires to the central rod and to the sleeve.

5. In the device of class specified, a socket-attaching member comprising a threaded socket electrically connected to a line-wire, a ring of insulating material supported on a shoulder within said socket, a contact-plate supported by said ring and in electrical contact with an opposite line-wire, and a securing-block of insulating material acting to hold said contact-plate in position.

6. A voltaic pile comprising a centrally-arranged rod of conducting material, a tube of insulating material surrounding the same, alternate layers of positive and negative electric elements arranged in series, disks of absorbent material situated between adjacent elements of opposite proportion, and separating-sleeves of insulating material arranged around the tube at the central portions of the absorbent disks to prevent compression of said disks, substantially as specified.

7. A voltaic pile comprising in combination, a centrally-arranged rod of conducting material, a tube of insulating material surrounding the same, perforated disks of positive and negative proportion arranged on said tube, disks of absorbent material disposed between adjacent elements and having central perforations of a diameter greater than those formed in the elements, and separating-sleeves of non-conducting material fitting around the tube and arranged in the central perforation of each of the absorbent disks, and a clamping-nut provided on the said central rod, substantially as specified.

701,254. MILLIARD-TABLE CUSHION. MORRIS BRUNSWICK, Chicago, Ill., assignor to the Brunswick-Balke-Clender Company, Chicago, Ill., a Corporation of Ohio. Filed Jan. 21, 1902. Serial No. 91,962. (No model.)

Claim.—A billiard-cushion strip composed of a suitable rubber compound, having some suitable face-hardening device molded in; united with the mass of compound by the vulcanizing process to which the latter is subjected; and located so far within the mass, as specified, that the wear, or playing-surface of the cushion, will not be overworn, or injuriously affected by the proper vulcanizing of the strip; all substantially as and for the purposes hereinbefore set forth.

701,955. LAWN-MOWER. WILLIAM BORN, St. Paul, Minn. Filed Aug. 28, 1900. Serial No. 28,300. (No model.)

Claim.—1. In combination with a lawn-mower frame and handle, and brackets swivelled to the sides of said frame and having heads at their outer ends; a grass-catching receptacle comprising a frame of wire having its front ends bent downward and removably engaged with said brackets inside their heads, a handle secured to this frame, and means for detachably connecting this handle with the handle of the lawn-mower.

2. In combination with a lawn-mower frame and handle, and brackets carried by the former; a grass-catching receptacle comprising a frame of wire whose front ends detachably engage said brackets, a handle connected to the rear of said frame, wires diverging from the front end of this handle and connected with the sides of the frame, and a hook on the lawn-mower handle detachably engaging the handle of the frame.

3. In combination with a lawn-mower frame and handle, and brackets carried by the frame; a grass-catching receptacle whose front ends detachably engage with said brackets, a straight handle rigidly secured to the rear of said receptacle, said handle projecting rearwardly parallel with the mower-handle when the receptacle is in position, and a hook detachably supporting said receptacle-handle underneath said mower-handle.

701,956. FLUID-CLEANER. JOHN S. CLARK, St. Clair, Mich., assignor of one-half to WILLIAM SCOTT MITCHELL. Filed Jan. 12, 1902. Serial No. 28,400. (No model.)

Claim.—1. In a fluid-cleaner, in combination, a spindle having right and left hand screw-threads, traveling spreaders thereon, a collar having radial slots loosely mounted on the spindle, radially-yielding segments arranged around and connected to the spindle and having projections engaging said slots, and scraper-blades attached to alternate segments.

2. In a fluid-cleaner, in combination, a spindle, a radially-slotted collar thereon, blade-bearing segments arranged around and flexibly attached

to the spindle, said segments having projections engaging the slots to guide the radial motion of the segments, and inclined spurs on the segments projecting in advance of the cutting edge of the blades.

3. In a fluid-cleaner, in combination, a spindle, a radially-slotted collar thereon, segments arranged around and flexibly attached to the spindle, said segments having projections engaging the slots to guide the radial motion thereof, and scraper-blades attached to the alternate segments, so that the free segments cover the space between the ends of the blades.

4. In a fluid-cleaner, in combination, a threaded spindle, a radially-slotted collar loosely mounted thereon, said threads being right and left hand on opposite sides of the collar, blocks loosely mounted on opposite ends of the spindle, springs attached to said blocks, traveling spreaders on the threaded portions of the spindle and engaging the springs to expand the same, segments attached to the free ends of the springs and having projections engaging the slots of the collar, and scraper-blades attached to the segments.

701,957. HAY-STACKER. JAMES H. CURT, Windsor, Colo. Filed Aug. 12, 1901. Serial No. 71,004. (No model.)

Claim.—1. In a hay-stacker, the combination with a suitable relatively stationary framework, of a lifting-frame hinged or pivoted thereon, a stacker-head slidably connected with said lifting-frame, and a link connection between the rigid part of the stacker-head and the frame, the point of connection with the frame being above the plane of the stacker-head when the latter is in its lowermost position, whereby the latter is projected outwardly from the stationary frame as the lifting-frame is raised.

2. In a stacker, the combination with a relatively stationary frame, of a lifting-frame pivoted on the stationary frame, a stacker-head slidably connected with the pivoted frame, and a link connecting a rigid part of the head with the stationary frame, the point of the framework where the link is connected being above the pivoted point of the lifting-frame, whereby as the lifting-frame is raised the head is extended or moved outwardly thereon.

3. In a stacker, the combination with a relatively stationary frame, of a lifting-frame hinged or pivoted thereon, a head having bars rigidly connected therewith and slidably connected with the pivoted frame, and links connected with the rigid head-bars at one extremity and with the stationary frame at the opposite extremity at a point above the pivoted point of the lifting-frame.

4. In a stacker, the combination with a relatively stationary frame, of a lifting-frame hinged or pivoted on the stationary frame, suitable hoisting devices mounted on the stationary frame and connected with the lifting-frame, in suitable operative relation, a stacker-head slidably connected with the lifting-frame, and links connected with a rigid part of the stacker-head at one extremity and with the stationary frame at the opposite extremity at points above the lifting-frame pivot, for extending the stacker-head or moving it outwardly on the lifting-frame.

5. In a stacker, the combination with a relatively stationary frame, of a lifting-frame hinged or pivoted thereon, hoisting means connected with the lifting-frame, a counterweight also connected with the lifting-frame and suspended on the stationary frame, a stacker-head slidably connected with the lifting-frame, and links pivoted on the stationary frame above the lifting-frame pivot, and connected with a rigid part of the stacker-head for extending the said head on the lifting-frame as the head is raised with the last-named frame.

6. The combination with a suitable stationary frame, of a lifting-frame pivotally connected with the stationary frame and having two parallel bars, a stacker-head provided with two bars rigidly connected with the head proper and slidably connected with the parallel bars of the lifting-frame, and links or arms connected with the rigid bars of the head at one extremity and with the stationary frame at the opposite extremity, at points above the pivoted points of the lifting-frame.

7. In a stacker, the combination with a relatively stationary frame, of a lifting-frame pivoted on the stationary frame, a stacker-head having bars rigidly connected therewith, guides secured to the bars of the stacker-

head and passing around the adjacent bars of the lifting-frame forming a sliding connection between the two sets of bars, and links connected with said guides at one extremity and with the stationary frame at the opposite extremity at points above the pivot of the lifting-frame.

701,258. PEANUT-ROASTER AND POPCORN-POPPER. WILLIAM T. CHASE, San Francisco, Cal., assignor to Simon Emanuel and James Howard Stevens, trustees, San Francisco, Cal. Filed Mar. 14, 1902. Serial No. 94,297. (No model.)

Claim.—1. In a device of the character described, a vessel adapted to hold popcorn, peanuts, chestnuts or the like composed entirely of asbestos, and a metallic frame around said vessel for supporting the same, substantially as described.

2. In a device of the character described, a vessel for holding popcorn, peanuts, chestnuts or the like made of asbestos compressed and molded into shape, and a metallic frame outside said vessel for supporting the same, substantially as described.

3. A popcorn-popper comprising a vessel entirely composed of asbestos, a metallic frame around the same having a handle, and a stop-pivot in the center thereof, in combination with a gas-burner having a socket to receive said stop-pivot, legs upon which it is supported and a ring burner around said socket provided with means for supplying gas thereto, substantially as described.

701,259. RAIL-TIE. HUGH DE HAVEN, Brooklyn, N. Y. Filed Dec. 2, 1901. Serial No. 94,294. (No model.)

Claim.—1. A bale-tie provided with a back bar and a double loop at one end adapted to receive the ends of a strap, one end of the said strap being anchored by engagement with both of the loops and a series of fingers projecting from the said back bar and adapted to engage and retain a strap passing through one of the loops, and having its free end interwoven with the fingers.

2. In a bale-tie the combination of a back bar and a plurality of loops at or near one end, the said loops being separated by a cross-bar, one of the said loops being larger than the other and adapted to receive both of the free ends of the strap, the other of said loops being adapted to cooperate with its mate to firmly anchor one of the free ends of the strap, and a series of fingers adapted to cooperate with the larger loop to hold the other free end of the strap.

3. In a bale-tie, the combination of means for anchoring one end of the bale-tie combined with means for anchoring the other end thereof, the said last-mentioned means comprising a series of fingers, each finger having a front edge inclined to the axis of the tie and a rear edge of substantially right angles thereto and adapted to engage the strap.

4. In a bale-tie the combination of a back bar having a loop at or near one end and a series of fingers at or near the other end, the said fingers having inclined front edges and rear edges substantially at right angles to the axis of the tie and adapted to engage the strap.

5. A bale-tie embodying in its structure a back bar and a plurality of loops at or near one end and a series of pointed fingers at or near the other end having their front edges inclined with respect to the axis of the bale-tie.

6. The combination of cross-bars a, c, a strap passing around the middle cross-bar d and beneath the edge of cross-bar c, and fingers h, i, j, the other end of the said strap passing around the cross-bar c and under and over adjacent fingers h, i, j.

701,260. TIPPING-MACHINE. PAUL C. DUNDON, Chicago, Ill., assignor of one-half to A. W. WARD, Chicago, Ill. Filed June 7, 1901. Serial No. 94,084. (No model.)

Claim.—1. In a machine for tipping cans, the combination of a tipping implement, means for advancing the can while being tipped, normally inactive, but permanently in readiness to operate thereon, means for imparting motion to said advancing means and tipping implement independently of the can, and means adapted to be released by the can for arresting the operation of the last-said means, substantially as set forth.

2. In a tipping-machine, the combination of a tipping implement, means for advancing the can while being tipped, means independent of the can operatively related to and exerting a permanent tendency on said tipping implement and advancing means for actuating them, and a resistance adapted to be released by the can, for restraining the operation of said tipping implement and advancing means, substantially as set forth.

3. In a tipping-machine, the combination of a tipping implement, means for advancing the can while being tipped, normally inactive and permanently in readiness to operate thereon, means for imparting motion to said advancing means and tipping implement independently of the can, means adapted to be released by the can for arresting the operation of the last-said means, and means for feeding the cans into the embrace of said can-advancing means, substantially as set forth.

4. In a tipping-machine, the combination of a tipping implement, means for guiding a can past said implement, a pivoted counterbalanced frame in which said implement is pivoted on an independent axis, and means for pulling said implement toward the can and longitudinally of the movement thereof, substantially as set forth.

5. In a tipping-machine, the combination of a tipping implement, means for guiding a can past said implement, a pivoted counterbalanced frame, a second frame pivotally mounted on said first frame and in which said implement is adjustably clamped, and means for pulling said implement toward the can and longitudinally of the movement thereof, substantially as set forth.

6. In a tipping-machine, the combination of a tipping implement, means for guiding a can past said implement, a pivoted counterbalanced frame, a second frame pivotally mounted on said first frame, clips or clamps holding said implement on said second frame, with capability of axial and transverse adjustment, and means for oscillating said frames for holding the implement against the can, substantially as set forth.

7. In a tipping-machine, the combination of a tipping implement, means for guiding a can past said implement, a pivoted counterbalanced frame, in which said implement is pivoted on an independent axis, and means flexibly connected with said implement for holding it in contact with the can, substantially as set forth.

8. In a tipping-machine, the combination of a tipping implement, means for guiding a can past said implement, a pivoted counterbalanced frame, in which said implement is pivoted on an independent axis, and means for oscillating said implement lengthwise of the line of movement of the can, substantially as set forth.

9. In a tipping-machine, the combination of a tipping implement, means for guiding a can past said implement, a pivoted counterbalanced

frame, in which said implement is pivoted on an independent axis, means for oscillating said implement lengthwise of the line of movement of the can and holding it in contact therewith while going with the can, and means for lifting said implement above the can when going in the opposite direction, substantially as set forth.

10. In a tipping-machine, the combination of a tipping implement, means for guiding a can past said implement, a pivoted counterbalanced frame in which said implement is pivoted on an independent axis, and means for pulling said implement downwardly and laterally, lengthwise of the line of movement of the can, substantially as set forth.

11. In a tipping-machine, the combination of a tipping implement movable axially and transversely, means yieldingly connected with said implement for oscillating it transversely, and means for holding said implement elevated during one of its transverse movements, substantially as set forth.

12. In a tipping-machine, the combination of a tipping implement yieldingly supported, so as to conform to the can to be tipped, and means for oscillating the point of said implement transversely in two different lines of movement, whereby it will touch the can going one way and be aloof from the can going the other way, substantially as set forth.

13. In a tipping-machine, the combination of a tipping implement movable axially and transversely, a sling movable transversely with said implement and having a shoulder, and means movable axially and transversely with said implement and adapted to engage said shoulder and support the implement against downward movement when oscillating in one direction, substantially as set forth.

14. In a tipping-machine, the combination of a tipping implement movable axially and transversely, a swinging sling having a shoulder, movable with said implement transversely, and also having a limited, independent movement thereof, and a leg operatively connected with said implement and adapted to engage said shoulder, for supporting said implement against axial movement when oscillating in one direction, substantially as set forth.

15. In a tipping-machine, the combination of a tipping implement movable transversely and axially, a swinging sling movable transversely with said implement and also independently thereof, and provided with a shoulder on one side and a notch or depression on the other side, and a leg operatively connected with said implement and arranged to engage alternately with said shoulder and in said notch, substantially as set forth.

16. In a tipping-machine, the combination of a tipping implement, a pivoted frame, in which said implement is pivotally supported on an independent axis, a swinging sling, having its axis of oscillation concentric with said independent axis, and provided with a shoulder, and a leg movable with said implement and adapted to rest upon said shoulder, as the implement moves in one direction, substantially as set forth.

17. In a tipping-machine, the combination of a tipping implement movable transversely and axially, a sling having a shoulder on one side and a depression on the other, and being movable transversely with said implement, a leg operatively connected with said implement and movable in unison therewith, and adapted to rest alternately in said depression and upon said shoulder, and means yieldingly connected with said implement for first pulling it axially and causing said leg to engage in said depression, and then transversely and upwardly, causing the shoulder to drop into engagement with said leg, substantially as set forth.

18. In a tipping-machine, the combination of a tipping implement movable axially and transversely, and a crank yieldingly connected with said implement, for imparting the said movements thereto, substantially as set forth.

19. In a tipping-machine, the combination of a tipping implement movable axially and transversely, and a crank elastically connected with said implement for imparting the said movements thereto, substantially as set forth.

20. In a tipping-machine, the combination of a tipping implement movable axially and transversely, a crank, and a bowed spring connecting said crank with said implement, for imparting the said movements thereto, substantially as set forth.

21. In a tipping-machine, the combination of a tipping implement movable axially and transversely, a crank, on elastic connection between said crank and implement, and means for rocking said crank back and forth throughout a partial revolution, for imparting the said axial and transverse movements to said implement, substantially as set forth.

22. In a tipping-machine, the combination of a tipping implement movable axially and transversely, the pivoted swinging sling 74 movable transversely therewith, a leg operatively connected with said implement and movable in unison therewith and engaging in said sling, said sling having a shoulder on one side for supporting said leg, a bowed spring operatively connecting said crank and tipping implement together, and means for rocking said crank back and forth a partial revolution, substantially as set forth.

23. In a tipping-machine, the combination of a tipping implement,

movable axially and transversely, means for yieldingly supporting said implement, a crank operatively and yieldingly connected with said implement, for oscillating it, and a rest operatively connected with said implement and adapted to engage said crank for holding said implement against downward or axial movement independently of said crank, substantially as set forth.

24. In a tipping-machine, the combination of a tipping implement, a crank operatively connected therewith, a guideway for the can, a turnstile operatively related to said guideway, and means for operatively connecting said turnstile with said crank for operating the tipping implement, substantially as set forth.

25. In a tipping-machine, the combination of a tipping implement, a crank operatively connected therewith, a guideway for the can, a turnstile having points or projections operatively related to said guideway and adapted to be engaged by the can, an oscillatory member operatively connected with said crank for oscillating the latter and operatively related to and adapted to be actuated by the points of said turnstile, substantially as set forth.

26. In a tipping-machine, the combination of a tipping implement, a crank operatively connected therewith, a guideway for the can, a turnstile operatively related to said guideway, an oscillatory member operatively related to and adapted to be thrown in one direction by said turnstile, a spring for throwing said member in the opposite direction, and means operatively connecting said member with said crank for oscillating the latter, substantially as set forth.

27. In a tipping-machine, the combination of a tipping implement, a crank operatively connected with said implement, a guideway for directing the cans past said implement, a turnstile operatively related to said implement and guideway, an oscillatory member operatively related to and adapted to be actuated by said turnstile, and a band operatively connecting said member and crank, substantially as set forth.

28. In a tipping-machine, the combination of a tipping implement, a guideway for directing the cans past said implement, a turnstile operatively related to said guideway and implement, means exerting a permanent tendency to revolve said turnstile, means for arresting the rotation of said turnstile, adapted to be released by the cans on said guideway, and means for imparting the movement of said turnstile to said tipping implement for actuating the latter, substantially as set forth.

29. In a tipping-machine, the combination of a tipping implement, a guideway for directing the cans past said implement, a turnstile operatively related to said implement and guideway, a friction-clutch operatively connected with said turnstile, means for permanently driving said clutch, means for arresting the rotation of said turnstile, arranged to be released by the cans on said guideway, and means for imparting the movement of said turnstile to said tipping implement for actuating the latter, substantially as set forth.

30. In a tipping-machine, the combination of a tipping implement, a guideway for the can, a turnstile operatively related to said implement and guideway, means for imparting a constant relative tendency to said turnstile, means for arresting the rotation of said turnstile, arranged to be released by the cans on said guideway, and means operatively connecting said member with said tipping implement, substantially as set forth.

31. In a tipping-machine, the combination of a tipping implement, a guideway for the can, a turnstile operatively related to said implement and guideway, and having radial projections or points, means for imparting a constant relative tendency to said turnstile, means for arresting the rotation of said turnstile, arranged to be released by the cans on said guideway, an oscillatory member arranged in the circle described by said points and adapted to be struck thereby, and moved in one direction, means for throwing said member in the opposite direction, and means operatively connecting said member with said tipping implement, substantially as set forth.

32. In a tipping-machine, the combination of a tipping implement, a guideway for the can, a turnstile operatively related to said implement and guideway and having radial points, means for imparting a constant relative tendency to said turnstile, a dog arranged to be engaged by said points for arresting the rotation of said turnstile, a trigger, projecting across said guideway and operatively connected with said dog, whereby the cans will release the latter, and means for imparting the movement of said turnstile to said tipping implement, substantially as set forth.

33. In a tipping-machine, the combination of a tipping implement, a guideway for the can, a turnstile operatively related to said implement and guideway, means for imparting a constant relative tendency to said turnstile, a pivoted dog for arresting the rotation of said turnstile, a trigger pivotally connected to said dog and projecting across said guideway at one end, a bell-crank, pivotally connected with the other end of said trigger, a spring having abutment against said dog and connection with

mid bell-crank, and means for imparting the movement of said turntable to said tipping implement, substantially as set forth.

34. In a tipping-machine, the combination of a tipping implement, means for controlling the same, and means for feeding the roller thereto operatively connected with means for operating the tipping implement, substantially as set forth.

35. In a tipping-machine, the combination of a tipping implement, a guideway for the same, a turntable operatively related to said implement and guideway, and having points, a roller-holder, feeding mechanism for the roller in said holder, having a member located in the circle described by said points, for actuating the same, and means for imparting the motion of said turntable to said tipping implement, substantially as set forth.

36. In a tipping-machine, the combination of a tipping implement, a cam-conveyor, guideways for the same on said conveyor, a turntable operatively related to said implement and guideway, means for imparting a constant relative tendency to said turntable, means for arresting the rotation of said turntable, having a trigger projecting across the path of the cam and adapted to be released thereby, means for imparting the movement of said turntable to said tipping implement, and a spring arranged opposite said trigger for overriding the same thereagainst, substantially as set forth.

37. In a tipping-machine, the combination of a tipping implement, relatively adjustable guideways for the same, a trigger projecting across the path of the cam on said guideways, a spring for returning the cam after engaging said trigger, secured to one of said guideways and being movable therewith at an oblique angle to the line of movement of said cam, and means for actuating said tipping implement when said trigger is engaged, substantially as set forth.

701,261. HYDRAULIC-MACHINE. FREDERICK B. GLASS, Quincy, Mass., assignor to Perkins Machinery Company, Boston, Mass., a Corporation of West Virginia. Filed Mar. 25, 1902. Serial No. 63,764. (No model.)

Claim.—1. The combination with the longitudinally and laterally movable punch; of the lever act, the upper act normally standing substantially in line therewith; a spring normally holding said upper act, said spring yielding when the said upper act is engaged by the punch and restoring said upper act when the punch rises from the material; and a portion of the upper act adapted to engage the side of the punch to guide and position the upper act.

2. The combination with the longitudinally and laterally movable punch; of a presser-foot; a lower act; an upper act movably mounted in said presser-foot and provided with a restoring-spring, said upper act normally standing over the lower act but being moved out of the way by the punch; and supporting and engaging portions of the punch to support and guide the act during the cutting or shearing operation.

3. In a cutting-machine, a lower act; a presser-foot to retain the material during the cutting operation; an upper act contained in said presser-foot; means for moving said upper act into alignment with said lower act after the punching operation; and a punch arranged to move laterally in said lower act, and to move said upper act out of alignment with said lower act.

4. In an oscillating-machine, a punch adapted to punch and feed the material; a lower act; a presser-foot; and an upper act spring-supported in said presser-foot and normally standing over the lower act, said upper act being moved out of the way by the punch in the feeding movement thereof.

701,263. HYDRAULIC-MACHINE. FREDERICK B. GLASS, Quincy, Mass., assignor to Perkins Machinery Company, Boston, Mass., a Corporation of West Virginia. Filed Apr. 6, 1901. Serial No. 64,607. (No model.)

Claim.—1. In an oscillating-machine provided with a gang of punches and a gang of cutting devices, a gage adjacent to the punches and cutting devices, and having an elongated gaging portion to extend some distance along the edge of the material, said gage being movable around an axis midway between the ends of the gang of tools; and means for automatically moving said gage on said axis after each cutting operation, as set forth.

2. In an oscillating-machine provided with a gang of punches, an edge-gage for the material pivotally supported at a point midway between the ends of said gang of punches; stops to limit the pivotal movement thereof; an actuating member connected with said gage; and means

for moving said member in one direction at the end of one cycle of operations, and in the other direction at the end of the next cycle of operations, as set forth.

3. In an oscillating-machine of the class described, the pivotally-supported edge gage for the material; an operating-rod connected with said gage to produce a movement thereof on its pivot; a cam cooperating with said rod arranged to produce a movement thereof in one direction substantially at the end of half a revolution of said cam, and a movement thereof in the other direction substantially at the end of the other half-revolution; and means for connecting the said cam with the operating-shaft of the machine to cause the said cam to make one revolution at each two revolutions of said shaft, as set forth.

4. In an oscillating-machine of the class described, a gage for the edge of the material pivotally supported; a reciprocating operating member for moving the said gage on its pivot; adjustable stops to limit the pivotal movement of said gage in either direction; and a yielding connection between the said gage and the said reciprocating operating member, as set forth.

5. In a machine for oscillating sheet-rollers in which bearing-rolls have been previously inserted, the combination with means for punching a plurality of holes in the material and cutting a plurality of cycles therein by a single cycle of operation; of a gage for the material so positioned as to cooperate with a previously-inserted bearing-roll, substantially as described.

6. In an oscillating-machine for consecutively cutting a gang of cycles in the right and left members of a sheet-roller, an end gage for each of said members; and an adjusting device for the said end gages which is common to both, as set forth.

7. In an oscillating-machine for consecutively cutting cycles in the two members of an upper previously supplied with bearing-rolls; a gage for each member of the upper below the support for the material to cooperate with one of the bearing-rolls; an adjusting-piston; and a rack connected with each gage, the said racks intermeshing with opposite sides of the said piston whereby the said gages may be equally adjusted in opposite directions at one operation, as set forth.

8. In an oscillating-machine, the combination with a tubular punch provided with an annular shearing-surface; of an anvil to cooperate with the said punch in perforating the material; means for bringing the said punch and anvil together; a spring-support for the material normally projecting above the said anvil and having an opening for the punch and anvil, the strength of the springs for said support being sufficient to force the material onto the punch after the material is perforated, substantially as described.

701,268. HYDRAULIC-MACHINE. FREDERICK B. GLASS, Quincy, Mass., assignor to Perkins Machinery Company, Boston, Mass., a Corporation of Massachusetts. Filed Oct. 29, 1901. Serial No. 66,478. (No model.)

Claim.—1. In an oscillating-machine, the combination with a punch having a longitudinal movement to punch the material; of a cutting-die connected with a rigid support to thereby contain the thrust; means for laterally moving said cutting-die into and out of alignment with the longitudinal axis of said punch; and a cooperating setting-die, as set forth.

2. In an oscillating-machine, the combination with a punch; of means for reciprocating said punch to perforate the material; a setting-die having a pivotal support which does not partake of the reciprocating movement of the punch; means for connecting the said punch with said setting-die whereby the latter is swung into and out of alignment with the punch in response to the reciprocating movement thereof; and a cooperating setting-die, as set forth.

3. In an oscillating-machine, the combination with a punch having a reciprocating movement; of a laterally-movable carrier for said punch; a setting-die having a pivotal connection with said carrier; means for swinging said die on said pivot into and out of alignment with said punch; and a cooperating setting-die, as set forth.

4. In an oscillating-machine, a reciprocating punch; a setting-die having a support stationary with relation to the punch; adjustable means for connecting said die with said punch; and a cooperating setting-die, as set forth.

5. In an oscillating-machine, a reciprocating punch; a setting-die having a pivotal support; a link connecting said punch with said die; and a cooperating setting-die, as set forth.

6. In an oscillating-machine, a punch having a reciprocating movement; a laterally-movable carrier for said punch; a setting-die having a pivotal connection with said carrier; a link connecting said punch with said die; and a cooperating setting-die, as set forth.

701,264. GAGE-ROD. ALFRED J. GRAY, Fitch, Wis., assignor of one-half to Eugene A. Gray, St. Paul, Minn. Filed May 14, 1901. Serial No. 66,482. (No model.)

Claim.—1. A gage-rod, comprising a barrel, a striking-pin and a hammer therein, means yieldingly connecting the striking ends of said pin and hammer, and means provided near the end of said barrel for co-operating with said pin to hold it stationary while the hammer is being retracted, substantially as described and for the purpose specified.

2. A gage-rod, comprising a barrel, a striking-pin and an actuating-hammer therein, means provided within said barrel between the striking ends of said pin and hammer for yieldingly holding them together but permitting the hammer to be retracted to drive forward the pin when released, substantially as described.

3. The combination, with a barrel having a tapered surface, of a striking-pin having a correspondingly-shaped surface to engage the tapered surface of said barrel, a hammer, and means for actuating the same to project said pin, substantially as described.

4. The combination, with a barrel, of a striking-pin adapted to be wedged in the end thereof, and a spring-actuated hammer, substantially as described.

5. The combination, with a barrel having a tapered ferrule in its end, of a striking-pin having a sleeve or collar to engage said ferrule, and a spring-actuated hammer for projecting said pin.

6. The combination, with a barrel, of a striking-pin adapted to be normally wedged in the end thereof, and means for actuating said pin.

7. The combination, with a barrel having a tapered ferrule in its end, of a striking-pin provided with a surface having a corresponding taper to engage said ferrule, a hammer, and means for actuating said hammer to project said pin, substantially as described.

8. The combination, with a barrel, of a striking-pin, an actuating-hammer, a spring interposed between said pin and hammer and having its ends attached thereto respectively, whereby when the hammer is withdrawn the pin will be retracted also and driven forward by the impact of the hammer when released.

9. The combination, with a barrel having a tapered ferrule in its end, of a striking-pin having a sleeve provided with a corresponding taper to engage said ferrule, and a spring-actuated hammer for projecting said pin.

10. In a gage-rod, the combination, with a barrel of a striking-pin provided in one end of said barrel, a hammer in the opposite end, a coil-spring provided between the striking ends of said pin and hammer and yieldingly connecting the same, said spring being normally under tension to hold said pin stationary in the end of the barrel and being put under greater tension when said hammer is retracted to project said pin when the hammer is released, substantially as described.

701,265. SLOW-CLOSING DEVICE FOR HYDRAULIC-ELEVATOR VALVE. LOUIS E. KAMMERER, New York, N.Y., assignor to the Franger Elevator Company, Worcester, Mass. Filed May 24, 1902. Serial No. 68,668. (No model.)

Claim.—1. The combination with a three-way valve which is adapted to be closed when in an intermediate position, of a slow-closing device

having a moving part thereof connected to said valve, means for permitting the movement of said moving part at a predetermined speed from an intermediate position in either direction, and means for restricting the speed at which it may be moved toward said intermediate position.

2. The combination with a hydraulic-elevator valve which is adapted to be moved from an intermediate position to open the supply to and discharge from the elevator-cylinder, a slow-closing device connected to said valve, consisting of a cylinder, a piston therefor, means for permitting a free discharge of the fluid in said cylinder as the piston is moved toward either end of said cylinder, and means for restricting the supply of fluid to either end of said cylinder as said piston is returned to its intermediate position, whereby said valve may be opened quickly to supply or exhaust, but will be retarded in its movement to its closed position.

3. A device for regulating the opening and closing movements of a three-way valve, consisting of a cylinder, a piston therefor, means for permitting the unrestricted circulation of fluid past said piston when it is moved from an intermediate position in said cylinder in either direction, and means for automatically restricting the circulation past said piston as it is moved toward said intermediate position.

4. A slow-closing device for a three-way valve, consisting of a closed cylinder, a piston therefor, an enlarged passage connected to each end of said cylinder and to an intermediate portion thereof, check-valves in said passages arranged to permit a free flow of the fluid in said cylinder from either end toward the center thereof, and means for permitting a restricted flow toward either end of said cylinder.

5. A slow-closing device for a three-way valve, consisting of a closed cylinder, a piston therefor, an enlarged passage connected to each end of said cylinder and to an intermediate portion thereof, check-valves in said passages arranged to permit a free flow of the fluid in said cylinder from either end toward the center thereof, and a restricted by-pass around said check-valves.

6. A slow-closing device for a three-way valve, consisting of a closed cylinder, a piston therefor, an enlarged passage connected to each end of said cylinder and to an intermediate portion thereof, check-valves in said passages arranged to permit a free flow of the fluid in said cylinder from either end toward the center thereof, a restricted by-pass around said check-valves, and a valve in said by-pass for regulating the flow therethrough.

7. A slow-closing device for a three-way valve, consisting of a closed cylinder, a piston therefor, a passage connecting each end of said cylinder to an intermediate portion thereof, check-valves therein arranged to permit a free flow of fluid from the ends toward the middle of said cylinder, means for regulating the flow through said passages and means for permitting a restricted flow in the opposite direction.

8. The combination with a hydraulic-elevator valve, which when moved from its middle position in one direction will connect the elevator-cylinder with the supply and in the other direction with the exhaust, a slow-closing device for said valve consisting of a cylinder, a piston therefor, connected to a moving part of said valve, and arranged to be in the central position of its travel when the valve is in its closed position, means for permitting a free circulation past said piston as it is moved in either direction from its central position, and means for preventing a correspondingly free circulation past said piston as it is moved from one of its extreme positions to its middle position, substantially as described.

9. A device for regulating the opening and closing movements of

a three-way valve, consisting of a cylinder containing a fluid, a piston therefor, passages connected to said cylinder, means for alternately closing said passages as the piston is moved in different directions, and a constantly-open passage, relatively smaller than said first-named passages, through which fluid may flow when either of the first-named passages is closed.

10. A device for regulating the opening and closing movements of a three-way valve, consisting of a cylinder containing a fluid, a piston therefor, passages connected to said cylinder, means for alternately closing said passages as the piston is moved in different directions, a constantly-open restricted passage, relatively smaller than the first-named passages, through which the fluid may flow when either of said passages is closed, and means for regulating the flow through all of the above-named passages.

11. A device for regulating the opening and closing movements of a three-way valve, consisting of a cylinder containing a fluid, a piston therefor, means for permitting a free circulation of fluid past said piston as it is moved from the center of said cylinder toward either end thereof, means for permitting only a restricted return flow past said piston as it is moved toward the center of said cylinder, and means for gradually restricting the freedom with which the fluid may pass the piston as it is moved from either end toward the center of the cylinder, whereby the speed at which the piston may be returned is correspondingly reduced as it approaches the center of the cylinder.

12. A device for regulating the opening and closing movements of a three-way valve, consisting of a cylinder containing a fluid, a piston therefor, means for permitting a free circulation of fluid past said piston as it is moved from the center of said cylinder toward either end thereof, means for permitting only a restricted return flow past said piston as it is moved toward the center of the cylinder, and means for varying the freedom with which the fluid may pass the piston, whereby the speed at which the piston may be moved by the valve during such predetermined movements is correspondingly varied.

13. The combination with an elevator-valve which is adapted to be closed when in an intermediate position and be opened when moved in either direction from said position, an automatic speed-regulating device having a moving part thereof connected to said valve, means for permitting comparatively free movements of said moving part in either direction from an intermediate position, and means for automatically varying the speed at which said part may be returned from an extreme to said intermediate position, whereby the speed of said valve in its closing movements may be made different at different points therein.

14. The combination with an elevator-valve which is adapted to be closed when in an intermediate position and be opened when moved in either direction from said position, an automatic speed-regulating device having a moving part thereof connected to said valve, means for permitting comparatively free movements of said moving part in either direction from an intermediate position, and means for automatically varying the speed at which said part may be returned from either extreme to said intermediate position, whereby the speed of said valve in its closing movements may be made different at different points therein.

15. The combination with an elevator-valve which is adapted to be closed when in an intermediate position and opened when moved in either direction from said position, a slow-closing device comprising a piston and cylinder, one of which parts is fixed and the other movable, connections between the movable part of said device and said valve, whereby said piston is in an intermediate position with respect to said cylinder when said valve is in its closed position, means for permitting a comparatively free circulation of fluid past said piston when said valve is moved in either direction, and means for correspondingly restricting said circulation when said valve is returned to its closed position, so that the speed of said valve in closing is correspondingly reduced.

701,266. COVERED ROLLER FOR COTTON-MACHINES. OLIVER H. HATHAWAY, Central Falls, and WILLIAM H. BRUNNEN, Providence, R. I. Filed Dec. 2, 1899. Serial No. 33,696. (No model.)

Claim.—A top roll for use in cotton-machines, which comprises a spindle having a speed with square ends formed integral therewith at its center, a roller having a covering of cloth and an outer covering of leather mounted on each end of said spindle, said rollers having square ends engaging the ends of the spindle, their other ends extending in vertical alignment with the ends of the spindle, a washer carrying a flange and a shank, the shank being secured in the ends of the spindle with the flange engaging the outer end of the roller, and a screw concentric in said washer

extending through the shank and secured in the spindle, substantially as described.

701,267. SHEET-METAL FASTENING-CLASP. FREDERICK R. HENNE, Louisville, Ky., assignor of two-thirds to CURRAN PAPA and ALFRED THURSTON PAPA, Louisville, Ky. Filed Aug. 26, 1901. Serial No. 73,067. (No model.)

Claim.—1. A holding-clasp composed of a single piece of sheet metal, having a substantially vertical body provided with horizontal flanges at each lower corner, a tongue extending from the upper edge of the vertical body, a notch in the lower edge of said body and between the horizontal flanges, and points struck from the body and extending in opposite directions to the flanges, substantially as described.

2. A sheet-metal holding-clasp having a tongue projecting centrally from one edge and having a corresponding notch at the other edge and a bent flange at each side of said notch, and having integral points projecting from its back, substantially as described.

3. A holding-clasp of sheet metal having a body and flanges extending from one edge of said body, and having a central tongue extending from the other edge of said body, and having points struck from the body with their flat faces vertical, said points projecting in opposite directions from the flanges, substantially as described.

4. The combination with a barrel or package, of a holding-clasp of sheet metal, having its body lying against the chime of the package, a flange against the head of the package, integral points entering the inner face of the chime, and a tongue extending over the end and into the outside of the package, as set forth.

701,268. BELMORING HITCHING-STRAP. ARTHUR H. HOWARD and GEORGE F. LOW, Ogdensburg, N. Y. Filed Sept. 24, 1901. Serial No. 75,442. (No model.)

Claim.—1. In a hitching device, a strap-head carrying an abutment at its one end with a gravity-hook mounted in the strap-head beneath the abutment and having its ends playing on opposite sides of the abutment, and horizontally-movable means adapted for engagement with one end of said gravity-hook to secure the other end thereof in engagement with said abutment.

2. In a hitching device, a strap-head carrying an abutment and spring-pressed engaging means, a gravity-hook mounted intermediate of its length in the strap-head, one end of said hook playing between said abutment and spring-pressed means and adapted to be engaged by the latter, the other end of said hook playing on the opposite side of the abutment and adapted to form a locking engagement therewith.

3. In a hitching device, a strap-head comprising jaws and an abutment carried thereby, a gravity-hook mounted intermediate of its length between said jaws and adapted to have one of its ends engage said abutment, spring-pressed means mounted in the strap-head adapted for engagement with the opposite end of said hook, means carried by said means and operatively through an opening provided therefor in the strap-head whereby the first-named means may be retracted, a hollow flexible connection secured at its one end to the strap-head and adapted to have its other end secured in the stall, and means operating through said connection and secured to said spring-pressed means whereby the said means may be automatically retracted.

4. In a hitching device, a strap-head carrying an abutment, and having a gravity-hook mounted therein intermediate of its length, with its ends extending beyond said abutment in opposite directions, spring-actuated means adapted for engagement with one of said ends of the hook whereby the opposite end thereof forms a locking engagement with said abutment, and a connection secured to the strap-head and carrying means for retracting said first-named means, substantially as described.

5. In a hitching device, a strap-head carrying an abutment and

having a gravity-hook mounted intermediate of its length therein, the ends of said gravity-hook being free and extending on opposite sides of the abutment, and sliding spring-pressed means adapted to engage over one of said ends of the hook to cause the other end thereof to form a locking engagement with the other face of the abutment.

701,269. SWITCH-CLUSTER-OPERATING DEVICE. HARVEY HUBBELL, Bridgeport, Conn. Filed Sept. 4, 1901. Serial No. 74,267. (No model.)

Claim.—1. A switch-operating device for lamp-clusters comprising a plurality of switch connections, a single operating connection, and a freely-movable coupling member flexibly connecting the latter with the former, whereby the operating connection may be pulled to simultaneously operate a plurality of switches or may be deflected to one side and pulled to operate any one of the switches.

2. A switch-operating device for lamp-clusters comprising a plurality of switch connections, a single operating connection, and a freely-movable coupling member flexibly connecting the latter with the former, whereby the operating connection may be pulled to simultaneously operate a plurality of switches or may be deflected to one side and pulled to operate any one of the switches, said switch connections and operating connection being detachably secured to the coupling member.

3. A switch-operating device for lamp-clusters comprising a series of switch connections, an operating connection and a coupling member, said coupling member comprising a plate having holes to receive the connections and curves engaging the plate and having heads adapted to engage and lock the connections, said heads being provided with recesses which will permit the connections to pass when the recesses and the holes in the plate are in alignment.

4. A switch-operating device for lamp-clusters consisting of a series of switch connections, an operating connection and a coupling member, said coupling member comprising a plate having holes to receive the connections, curves engaging the plate and having heads adapted to engage and lock the connections, said heads having recesses which will permit the connections to pass when in alignment with the holes, a cover-plate through which the operating connection passes and which covers the ends of the switch connections and means for securing said plate together.

701,270. BELT. LOUIS BRUNNEN, Brooklyn, N. Y., assignor to Adolf Mayer, Brooklyn, N. Y., and Samuel Friedman, New York, N. Y. Filed Sept. 26, 1901. Serial No. 73,760. (No model.)

Claim.—1. A belt, consisting of a belt-band, a buckle at one end thereof, a backing-strip arranged under said buckle, and secured to the buckle end of said belt-band, and loops arranged at opposite ends of said backing-strip, substantially as set forth.

2. A belt, consisting of a belt-band, a buckle, a backing-strip of greater width than said belt-band, and arranged to lie under said buckle in an approximately central position, and a loop at each end of said backing-strip, substantially as set forth.

701,271. PROCESS OF REDUCING FIBROUS MATERIAL TO PULP. CHARLES T. LEE, Boston, Mass., assignor to Ragusa Pulp Company, a Corporation of Maine. Filed July 21, 1901. Serial No. 70,418. (No specimens.)

Claim.—1. That improvement in the art or method of reducing fibrous material to pulp, which consists in dampening the material, immersing the dampened material in chlorine gas, and washing the product in water, as set forth.

2. That improvement in the art or method of reducing fibrous material to pulp, which consists in cutting, stripping or otherwise breaking up the material, dampening the same, immersing the dampened material in chlorine gas, and washing the product in water, as set forth.

3. That improvement in the art or method of reducing fibrous material to pulp, which consists in cutting, stripping or otherwise breaking up the material, dampening the same, immersing the dampened material in chlorine gas, and washing the product in water, as set forth.

4. That improvement in the art or method of reducing fibrous material to pulp, which consists in subjecting such material when damp to the action of chlorine gas, substantially as and for the purpose described.

5. That improvement in the art or method of reducing fibrous material to pulp, which consists in dampening the material and then subjecting it to the action of chlorine gas, substantially as and for the purpose described.

6. That improvement in the art or method of reducing fibrous material to pulp, which consists in subjecting such material when damp to the action of chlorine gas, washing the product in water, and subjecting the product to a bleaching agent, and again washing the same, substantially as described.

7. That improvement in the art or method of reducing lignose to pulp, which consists in subjecting the lignose when damp to the action of chlorine gas; substantially as described.

8. That improvement in the art or method of reducing lignose to a pulp, which consists in dampening the lignose and then subjecting it to the action of chlorine gas; substantially as described.

701,272. AIR-BRAKE CONNECTION. WILLIAM ENRI, Newark, N. J. Filed June 7, 1901. Serial No. 63,691. (No model.)

Claim.—1. The combination in an air-brake connection of the air-brake couplings A and A', the spiral steel tubing O and the woven hose B constructed with parallel, all constructed and combined substantially as hereinbefore described and shown.

2. The combination in an air-brake connection of the air-brake couplings A and A', the spiral steel tubing O coated with paraffin and the woven hose B saturated with paraffin, all constructed and combined substantially as hereinbefore described and shown.

3. The combination in an air-brake connection of the air-brake couplings A and A', the spiral steel tubing O and the woven hose B all constructed and combined substantially as hereinbefore described and shown.

701,278. SCALE. HORATIO R. CROOK, JR., Binghamton, N. Y., assignor of one-half to Daniel H. Winans, Binghamton, N. Y. Filed Dec. 19, 1901. Serial No. 95,496. (No model.)

Claim.—1. The combination with a scale-beam and poise, of a counterpoise on the beam, a weight-holder having a runway and series of weights adapted to move on said runway, said counterpoise and runway being arranged for the weights to pass over the runway to and from the counterpoise, and said runway being so constructed and arranged that any number of the weights may be transferred to the counterpoise while the remaining weights of the series are retained in the holder, substantially as described.

2. The combination with a scale-beam and poise, of a counterpoise on the beam, a weight-holder having a runway and series of spherical weights on said runway, said counterpoise and runway being arranged for the weights to roll over the runway to and from the counterpoise, and said runway being so constructed and arranged that any number of the weights may be transferred to the counterpoise while the remaining weights of the series are retained in the holder, substantially as described.

3. The combination with a scale-beam and poise, of a counterpoise on the beam having a spiral weight-runway, a stop at the bottom of the spiral runway for holding the weights, a weight-holder having a runway and series of weights, said counterpoise and holder being arranged for the weights to pass over the holder-runway to and from the spiral counterpoise-runway, substantially as described.

4. The combination with a scale-beam and poise, of a counterpoise on the beam having a spiral weight-runway adapted for spherical weights, a stop at the bottom of the spiral runway for holding the weights, a weight-holder having a runway and series of spherical weights, said counterpoise and holder being arranged for the weights to roll over the holder-runway to and from the spiral counterpoise-runway, substantially as described.

5. The combination with a scale-beam and poise, of a counterpoise on the beam, a weight-holder having a runway and series of weights adapted to move on said runway, said counterpoise and runway being arranged for the weights to pass over the runway to and from the counterpoise and for change of the relative position of the counterpoise and runway from the weighing position in which the weights may pass from the runway to the counterpoise into a position for the return of the weights from the counterpoise, and said runway being so constructed and arranged that any number of the weights may be transferred to the counterpoise while the remaining weights of the series are retained in the holder, substantially as described.

6. The combination with a scale-beam and poise, of a counterpoise on the beam having a spiral weight-runway, a weight-holder having a runway and series of weights, said counterpoise and holder being arranged for the weights to pass over the holder-runway to and from the spiral counterpoise-runway, said counterpoise being normally in position to receive the weights at the top of the spiral runway and being mounted for return of the weights to the holder-runway from the bottom of the spiral runway, substantially as described.

7. The combination with a scale-beam and poise, of a counterpoise on the beam having a spiral weight-runway, a weight-holder having a runway and series of weights, said counterpoise and holder being arranged for the weights to pass over the holder-runway to and from the spiral counterpoise-runway and a releasable stop at the bottom of the spiral runway, substantially as described.

8. The combination with a scale-beam and poise, of a counterpoise on the beam having a spiral weight-runway, a weight-holder having a runway and series of weights, said counterpoise and holder being arranged for the weights to pass over the holder-runway to and from the spiral counterpoise-runway, a releasable stop at the bottom of the spiral runway, and means whereby said stop is released when the counterpoise is raised for returning the weights, substantially as described.

9. The combination with a scale-beam and poise, of a counterpoise on the beam having a spiral weight-runway, a weight-holder having a fixed runway inclined downward from the counterpoise and series of weights, said counterpoise being mounted for movement from the weighing position in which the weights may pass from the runway to the counterpoise into a position for the return of the weights from the counterpoise, substantially as described.

10. The combination with a scale-beam and poise, of a counterpoise on the beam having a spiral weight-runway, a weight-holder having a fixed runway inclined downward from the counterpoise and series of weights, said counterpoise being mounted for movement from the weighing position in which the weights may pass from the runway to the counterpoise into a position for the return of the weights from the counterpoise, a releasable weight-stop on the counterpoise, and means whereby said stop is released when the counterpoise is raised for returning the weights, substantially as described.

11. The combination with a scale-beam and poise, of a counterpoise on the beam adapted to receive a number of weights, and a weight-holder having a runway and series of weights adapted to move thereon to the counterpoise for weighing and to move thereon from the counterpoise when the weights that have been transferred to the counterpoise are raised for return to the runway, and said runway being so constructed and arranged that any number of the weights may be transferred to the counterpoise while the remaining weights of the series are retained in the holder, substantially as described.

12. The combination with a scale-beam and poise, of a counterpoise on the beam adapted to receive a number of weights, and a weight-holder having a fixed runway inclined downward from the counterpoise and series of weights adapted to move thereon to the counterpoise for weighing and to move thereon from the counterpoise when the weights that have been transferred to the counterpoise are raised for return to the runway, substantially as described.

13. The combination with a scale-beam and poise and a series of weights, of a counterpoise adapted to receive the weights and having a vertical spiral weight-runway, substantially as described.

14. The combination with a scale-beam and poise, of a weight-holder on the beam having a runway and series of hardened-steel-ball counterpoise-weights, said runway being so constructed and arranged that any number of the weights may be transferred over the runway into position for use as counterpoise-weights, while the remaining weights of the series are retained on the runway and the weights used may be returned to the runway after weighing, substantially as described.

15. The combination with a scale-beam and poise, counterpoise and weight-holder, of a series of hardened-steel-ball weights in the holder, said counterpoise and holder being constructed and arranged for the transfer of any number of said weights from the holder to the counterpoise for weighing while the remaining weights of the series are retained in the holder and for returning the used weights from the counterpoise to the holder after weighing, substantially as described.

16. The combination with a scale-beam and poise and a series of spherical weights and runway therefor, of a counterpoise adapted to receive the weights, and having the open vertical spiral weight-runway 19 and central bar 12, substantially as described.

17. The combination with the scale-beam, poise and weights, of the counterpoise having the weight-runway, a weight-stop at the bottom of the runway, and guard 20, substantially as described.

18. The combination with the scale-beam and poise, of the weight-holder I having the inclined runway 17, a series of spherical weights a on said runway, counterpoise H suspended from the beam and having a spiral runway adapted to receive the weights a from the runway 17 at the top of the spiral runway and be lifted for the return of the weights from the bottom of the spiral runway, a releasable stop for holding the weights in the counterpoise, and a cut-off at the top of the counterpoise adapted to close the holder I and prevent weights passing from the holder to the counterpoise when the scale-beam is lowered, substantially as described.

19. The combination with the scale-beam and poise, of the weight-holder I having the inclined runway 17, a series of spherical weights a on said runway, counterpoise H suspended from the beam and having a spiral runway adapted to receive the weights a from the runway 17 at the top of the spiral runway and be lifted for the return of the weights from the bottom of the spiral runway, a stop 3 for holding the weights in the counterpoise, and means for tripping said stop to release the

weights when the counterpoise is raised for returning the weights to the holder, substantially as described.

701,274. RECEPTACLE FOR ETHYLCHLORIDE. LOUIS BERWANGER, New York, N. Y., assignor to Anglo Chemical Works, Broomfield, N. J., a Corporation of New Jersey. Filed Feb. 6, 1908. Serial No. 95,771. (No model.)

Claim.—1. In a device of the class described, the combination with a tube, of a cap attached thereto, means substantially as described for making a tight joint between the tube and the cap, and a screw secured in said cap.

2. In a device of the class described, the combination with a tube, of a non-adjustable cap attached to the tube by a threaded joint, means for locking said cap against rotation and providing a tight joint between the tube and the cap, and a screw attached to the cap.

3. In a device of the class described, the combination with a tube, of a non-adjustable cap attached to said tube by a threaded joint, a washer and nut within said cap and locking the same against rotation on the tube and forming a tight joint between said parts, and a screw.

4. In a device of the class described, the combination with a tube, of a non-adjustable chambered cap attached to said tube by a threaded joint, an elastic washer within said chamber of the cap, a nut screwed on the tube and impinging the washer, and a screw.

5. A device of the class described comprising a tube, a cap thereon, a screw screwed into said cap and provided with capillary jet-passages and with two series of capillary ducts, said series of ducts communicating individually with said jet-passages, and said jet-passages being disposed in converging relation and opening at different points through the active end or face of the screw, and a valve adapted to close the tube.

6. A device of the class described comprising a chambered cap, a screw screwed into said cap and provided with converging jet-passages which are supplied by a plurality of branching ducts adapted to communicate with said chamber, said jet-passages opening at different points of the active end or face of the screw, and a valve carried by the screw within the branching ducts and adapted to close the source of supply to the chamber of said cap.

7. A device of the class described, provided with a threaded tube, a cap screwed to said tube, a disk screwed on the tube, a spring-washer acting against said disk and screwing the threads thereof into engagement with the threads of the tube, and an adjustable screw attached to the cap.

701,275. AUTOMATIC SIGNAL FOR ELECTRIC RAILWAYS. RALPH L. BROWN, Waterbury, Iowa, assignor to Western Railway Signal Company, Waterbury, Iowa. Filed July 25, 1901. Serial No. 95,670. (No model.)

Claim.—1. The combination with a frame supported above a trolley-wire and having openings, drop-blocks movable within said openings operated by gravity and fixed on their upper ends with conducting-plates, terminals adapted to make independent contact with said plates when the blocks are raised, a strip adapted to make contact with other plates when its block is raised, and circuits leading from said strip through a source of power and electromagnets to said terminals; of a spring-block supported by the frame between said drop-blocks and adapted so as to stand outside the trolley-wire, the spring-block being adapted when swung mechanically in either direction by a passing trolley-wheel to raise one of said drop-blocks and close the circuit, as and for the purpose set forth.

2. The combination with a frame supported above a trolley-wire and having openings, drop-blocks movable within said openings operated by gravity and fixed on their upper ends with conducting-plates, terminals adapted to make independent contact with said plates when the blocks are raised, a strip adapted to make contact with other plates when its block is raised, a main circuit including a source of power and the work to be performed, devices for making and breaking said main circuit, and a second circuit leading through said devices and a source of power to said terminals and plates; of means for permitting the trolley-wheel to pass beneath the first and to raise the second of said blocks mechanically when the car is passing in either direction, as and for the purpose set forth.

3. The combination with a frame supported above a trolley-wire and having openings, drop-blocks movable within said openings operated by gravity and fixed on their upper ends with conducting-plates, terminals adapted to make independent contact with said plates when the blocks are raised, a strip adapted to make contact with other plates when its block is raised, a main circuit including a source of power and the work to be performed, devices for making and breaking said main circuit, and

a second circuit leading through said devices and a source of power to said terminals and plates; of a spring-block suspended from the frame between the drop-blocks and adapted when swung in either direction by a passing trolley-wheel to raise one block mechanically and establish the second circuit above mentioned, as and for the purpose set forth.

4. The combination with two vertically-movable drop-blocks operated by gravity and fixed on their upper ends with conducting-plates, a supporting-frame having a projection between said blocks, terminals mounted on the projection and adapted to contact with other plates when its block is raised, and means for permitting a trolley-wheel to pass under the first of said blocks in either direction and to mechanically raise the second; of a dotted framework standing above the blocks, a strip centrally attached to said framework with its extremities adapted to contact with other plates when its block is raised, and circuits leading from said strip through a source of power and the work to be performed and to said terminals, as and for the purpose set forth.

5. The combination with two vertically-movable drop-blocks operated by gravity and fixed on their upper ends with conducting-plates, a supporting-frame having a projection between said blocks, terminals mounted on the projection and adapted to contact with other plates when its block is raised, and means for permitting a trolley-wheel to pass under the first of said blocks in either direction and to mechanically raise the second; of a dotted framework standing above the blocks, a strip centrally attached to said framework with its extremities adapted to contact with other plates when its block is raised, books standing above said extremities of the strip, and circuits leading through said books, a source of power, and the work to be performed, as and for the purpose set forth.

6. In an automatic signal for electric railways, the combination with drop-blocks movable vertically by impact upon them, of a trolley-wheel passing in either direction, and circuits including a source of power and two electromagnets through one of which an impulse is passed when a block is raised; of a second circuit including a pair of signals at opposite ends of the track-section, and devices for making and breaking this circuit which devices include two ratchet-wheels intermittently rotated when said magnets are alternately energized, as and for the purpose set forth.

701,276. LANTERN. GEORGE L. WILLIAMS, Calverton, Ill., assignor of one-half to F. Curtis Wilson, Chicago, Ill. Filed Aug. 15, 1901. Serial No. 71,097. (No model.)

Claim.—1. A lantern comprising a front casing closed at its front and open at its rear end, a rear casing closed at its rear and open at its front end, said casings being telescoped together and the outer casing being made smaller than the opening in the outer casing to afford venting-openings between them, and an inclined burner, substantially as described.

2. A lantern comprising an outer casing closed at its front and open

at its rear end, an inner casing open at its front and closed at its rear end, the inner casing being telescoped into the outer casing and made smaller in cross-section than the opening in the latter to afford ventilating-space between the casings, and an inclosed burner in the inner casing, substantially as described.

2. A lantern comprising an outer casing glazed at its front and open at its rear end, an inner casing open at its front and closed at its rear end, the inner casing being telescoped into the outer casing and made smaller in cross-section than the opening in the latter to afford ventilating-space between the casings, an annular shielding-flange at the rear of the ventilating-space, and an inclosed burner, substantially as described.

4. A lantern comprising an outer casing glazed at one end and open at the other, an inner casing telescoping into the open end of the outer casing and made smaller to provide an annular ventilating-space between the casings, a reflector in the inner casing facing toward the glazed end of the outer casing, and an inclosed burner.

5. A lantern comprising an outer casing, an inner casing telescoping into the outer casing and made smaller to afford a ventilating air-space between the casings, and an annular flange on the inner casing extending out behind the rear edge of the outer casing but separated therefrom so as to leave an outlet for the ventilating air-space.

6. A lantern comprising an outer casing, an inner casing telescoping into the outer casing, a spring-bearing between the casings, and an opposite latching device between the casings held normally in engagement by the pressure of the spring-bearing.

7. A lantern comprising an outer casing, an inner casing telescoping into the outer casing, a spring-bearing between the casings, and interlocking transverse and longitudinal ribs on the casings opposite the spring-bearing and normally held in engagement thereby.

8. A lantern comprising an outer casing, an inner casing telescoping into the outer casing, a spring supporting-plate in the outer casing against which the inner casing yieldingly rests, and latching members located between the casings opposite the spring-bearing and held normally interlocked thereby.

9. A lantern comprising an outer casing, an inner casing telescoping into the outer casing, a spring-bearing in the outer casing against which the inner casing yieldingly rests, longitudinal notched ribs on the outer casing opposite the yielding bearing, and a transverse rib on the inner casing normally held interlocked with the notched ribs by the pressure of the spring-bearing.

10. A lantern comprising an outer casing, an inner casing telescoping into the outer casing, a longitudinal rib on one casing and a transverse rib on the other casing interlocking therewith, said ribs being opposite the yielding bearing and normally held in engagement thereby, and steps embracing the longitudinal rib to prevent relative rotation of the casings.

11. A lantern comprising an outer casing, an inner casing telescoping into the outer casing and made smaller to provide a ventilating-space between the casings, a burner within the inner casing, a stem projecting forwardly through the rear wall of the casing and supporting the burner, a cross-bar on the casing behind its rear wall, and a fitting on said cross-bar to which said burner-stem is detachably connected.

REISSUES.

11,994. PNEUMATIC STRAW-SACKER. JOHN M. ANDREWS, Andrews, Tenn., assignor of two-fifths to A. P. Roberts and G. P. Roberts. Filed Feb. 7, 1902. Serial No. 98,092. Original No. 698,590. Issued Mar. 12, 1901.

Claim.—1. In a pneumatic straw-sacker, the combination of a stacker-tube having a master-wheel forming the pivotal support thereof, a loose pinion to rotate said master-wheel, a shaft and coupling steps to rotate said pinion and permit of the partial rotation of said shaft independently of said pinion, a shaft and connections to rotate said pinion-shaft, shifting mechanism to rotate said shaft in opposite directions alternately, and a shifting lever actuated by steps carried by said master-wheel, whereby said stacker-tube may be automatically swung from side to side and caused to "dwell" at the limits of its path at each change in the direction of its movement, substantially as described.

2. In a pneumatic straw-sacker, the combination of a stacker-tube having a master-wheel forming the pivotal support thereof, said master-wheel having sprocket-teeth, a loose sprocket-pinion, an endless sprocket-chain connecting said master-wheel and sprocket-pinion, a shaft and coupling steps to rotate said pinion and permit of the partial rotation of said shaft and connections to rotate said pinion-shaft, shifting mechanism to rotate said shaft in opposite directions alternately, and a shifting lever actuated by steps carried by said master-wheel, for the purpose set forth, substantially as described.

3. In a pneumatic stacker, the combination with the auxiliary discharge-tube thereof, of driving means therefor consisting in part of a gear, a shaft, a connection between said shaft and gear allowing a partial rotation of one independent of the other, and means for alternately driving one of said elements alternately in opposite directions.

4. In a pneumatic stacker, the combination with the auxiliary discharge-tube thereof, of driving-gear therefor consisting in part of a shaft, a gear mounted thereon, a pin carried by the shaft and a coupling pin carried by the gear in position to allow a relative rotation of the shaft or gear independent of the other, and means for automatically driving the independently-movable element alternately in opposite directions.

11,995. PROCESS OF MAKING SULFURIC ANHYDRIDE. HENRY S. RACKENBACH, Mount Vernon, N. Y. Filed Mar. 29, 1902. Serial No. 109,690. Original No. 694,022, dated Nov. 5, 1901.

Claim.—1. The process of producing sulfuric anhydride (SO₂), which consists in oxidizing sulfur dioxide by the action of metallic oxide, substantially as described.

2. The process of producing sulfuric anhydride, which consists in conveying sulfur dioxide in contact with metallic oxide at a temperature below the dissociating-point of sulfur trioxide.

3. The process of producing sulfuric anhydride, which consists in exposing a metallic oxide to the action of heated sulfur dioxide while maintaining the temperature below the dissociating-point of sulfuric anhydride.

4. The continuous process of producing sulfuric anhydride (SO₂) which consists in exposing metallic oxide to the action of sulfur dioxide at a temperature below the dissociating-point of sulfur trioxide, conveying the sulfur trioxide produced to a condenser, elevating the temperature of the metallic residue, passing oxygen over the same, cooling, separating the product to the action of more sulfur dioxide and continuing the process as before.

5. The process of producing sulfuric anhydride, which consists in exposing iron oxide to the action of sulfur dioxide in a heated state and maintaining the temperature below the dissociating-point of sulfuric anhydride, substantially as described.

6. The process of making sulfuric anhydride, which consists in oxidizing sulfur dioxide while maintaining the temperature below the dissociating-point of sulfur trioxide, substantially as described.

7. The process of producing sulfuric anhydride, which consists in conveying sulfur dioxide in contact with an oxidizing agent at a temperature below the dissociating-point of sulfur trioxide, substantially as described.

8. The process of making sulfuric anhydride, which consists in subjecting sulfur dioxide to the action of an oxidizing agent while maintaining the temperature below the dissociating-point of sulfur trioxide, substantially as described.

9. The process of making sulfuric anhydride, which consists in oxidizing sulfur dioxide and maintaining the temperature below the dissociating-point of sulfur trioxide by refrigeration, substantially as described.

10. The process of making sulfuric anhydride, which consists in mixing sulfur dioxide with oxygen while maintaining the temperature between the combining and dissociating points of sulfur trioxide by controlled heat and refrigeration, substantially as described.

11. The process of making a compound composed of one atom of sulfur and three atoms of oxygen which consists in mixing substances forming the compound while maintaining the temperature below the dissociating-point of sulfuric anhydride by refrigeration, substantially as described.

11,996. COMBINED SPOOL-HOLDER AND TENSION DEVICE FOR SEWING-MACHINES. ARTHUR I. JACOB, Hartford, Conn., assignor to the Smyth Manufacturing Company, Hartford, Conn., a Corporation of Connecticut. Filed Mar. 7, 1902. Serial No. 97,807. Original No. 698,022, dated Dec. 17, 1901.

Claim.—1. A combined spool-holder and tension device, comprising a base-plate adapted to support the spools or bobbins, a top plate conforming thereto and having eyes for the threads, and standards for supporting the top plate above the base-plate and means for supporting the same adjacent to the base-plate and in line with one another, an independent bar carried by the top plate having eyes for the threads whereby the threads from the spools or bobbins pass up through the eyes in the top plate, down through eyes in the bar supported thereby, through the tension device supported by the base-plate and so to the needles of the sewing-machine, substantially as set forth.

2. A combined spool-holder and tension device, comprising a main or base plate with spool-supports arranged on three sides of a rectangular figure, a top plate having eyes for the threads, and standards for supporting the top plate above the base-plate and conforming in outline to the base-plate, standards from the base-plate for supporting the top plate, a bar having eyes for threads secured to the top plate parallel with the main portion of the top plate, a bar and means for supporting the same adjacent to the base-plate and substantially beneath the bar carried by the top plate and which latter bar is parallel with the main portion of the base-plate and tension devices in line with one another supported by the bar of the base-plate, substantially as set forth.

3. A combined spool-holder and tension device, comprising a series of connected circular disks arranged on three sides of a rectangular figure and adapted to support the spools or bobbins, standards rising therefrom, a top plate having eyes for the threads and means for supporting the same upon and clamping the same to the standards, pins carried by the top plate, rising above the same and adapted to support auxiliary spools, a center-bar parallel with the longer portion of the top plate and having eyes agreeing in number with the eyes of the top plate plus the number of pins for auxiliary spools, a bar parallel with the longer portion of the base-plate, and means for connecting and supporting the same adjacent to

the base-plate and substantially below the bar carried by the top plate and tension devices supported by the latter bar, substantially as set forth.

4. A combined spool-holder and tension device, comprising a series of connected circular disks arranged on three sides of a rectangular figure and adapted to support the spools or bobbins, standards rising therefrom, a top plate having eyes for the threads and means for supporting the same upon and clamping the same to the standards, pins carried by the top plate, rising above the same and adapted to support auxiliary spools, a center bar parallel with the longer portion of the top plate and having eyes agreeing in number with the eyes of the top plate plus the number of pins for auxiliary spools, a bar parallel with the longer portion of the base-plate, and means for connecting and supporting the same adjacent to the base-plate and substantially below the bar carried by the top plate and tension devices supported by the latter bar, said tension devices each comprising a plate 7 with eyes through the same near the lower edge, pins 9 connecting said plates to the standard bar, spring-fingers 10 connected to said pins, and adjusting-screws 11 passing through the spring-fingers into interiorly-threaded holes in the said bar with the free ends of the spring-fingers bearing upon the plate 7, substantially as set forth.

5. A combined spool-holder and tension device, comprising a series of connected circular disks arranged on three sides of a rectangular figure and adapted to support the spools or bobbins, standards rising therefrom, a top plate having eyes for the threads and means for supporting the same upon and clamping the same to the standards, pins carried by the top plate, rising above the same and adapted to support auxiliary spools, a center bar parallel with the longer portion of the top plate and having eyes agreeing in number with the eyes of the top plate plus the number of pins for auxiliary spools, a bar parallel with the longer portion of the base-plate and means for connecting and supporting the same adjacent to the base-plate and substantially below the bar carried by the top plate, and tension devices supported by the latter bar, and flex-arms each comprising a wire helix and integral arm with an eye at the free end, the wire helix fitting into the opening in the spool and the eye at the end receiving the thread from the spool, substantially as set forth.

6. A combined spool-holder and tension device, comprising a base-plate adapted to support the spools or bobbins and having arms extending centrally toward one another, a top plate conforming thereto and having eyes for the threads and arms that also extend toward one another and come over the arms of the base-plate, said arms being perforated at their ends, standards for supporting the top plate above the base-plate, a bar and means for supporting the same adjacent to the base-plate and tension devices supported thereon, a bar carried by the top plate having eyes for the threads, and rods extending vertically through the ends of the arms of the base-plate and top plate and through the ends of the bar carrying the tension devices and the other bar having the eyes whereby said parts are connected together removably, substantially as specified.

11,997. INSULATED CONDUCTOR. ELIOT THOMSON, Swampscott, Mass., and JOHN S. GILLMAN, Lynn, Mass., assignors to General Electric Company, a Corporation of New York. Filed Apr. 24, 1902. Serial No. 104,794. Original No. 696,127, dated Mar. 11, 1902.

Claim.—1. An insulating compound consisting of an adherent non-explosive cellulosic ester attached to a support.
2. An insulating compound consisting of a non-explosive cellulosic ester attached to a support by an adhesive binder.
3. An insulated conductor coated with a non-explosive cellulosic ester.
4. An insulated conductor coated with a cellulosic ester bound to the conductor by an adhesive compound.
5. An insulated conductor coated with a waterproof heat-resisting compound of stramonium cellulose.
6. An insulated conductor coated with an acetate of cellulose.
7. An insulated conductor coated with succinate of cellulose.
8. An insulated conductor coated with a plurality of films of tetracetate of cellulose.
9. An insulated conductor covered with a film of rubber next the metal and an adherent covering of cellulosic tetracetate over the rubber.

DESIGNS.

85,922. ORNAMENTAL HEAD FOR BROOCHES, SCARF-TIPS, OR SIMILAR ARTICLES. LOUIS D. FRISSE, Newark, N. J., assignor to The Fins of Beavers and Browns, Newark, N. J. Filed Feb. 4, 1902. Serial No. 33,364. Term of patent 7 years.

Claim.—The design for an ornamental head for brooches, scarf-tips, and similar articles as herein shown and described.

85,923. SOUVENIR SPOON, FORK, OR SIMILAR ARTICLE. JOHN T. DUNN, St. Louis, Mo. Filed Dec. 7, 1901. Serial No. 35,112. Term of patent 24 years.

Claim.—The design for a souvenir spoon, fork, or similar article, substantially as herein shown and described.

85,924. ORNAMENTAL FRAME FOR TRAPOTS OR SIMILAR ARTICLES. HOWARD PIPERBERG, Washington, D. C. Filed Dec. 7, 1901. Serial No. 33,100. Term of patent 24 years.

Claim.—The design for an ornamental frame for trapots or similar articles, as herein shown and described.

85,925. PICTURE-FRAME. DAVID A. KIRK, Chicago, Ill., assignor to Chicago Picture Company, Chicago, Ill., a Corporation of Illinois. Filed Dec. 26, 1901. Serial No. 37,578. Term of patent 7 years.

Claim.—The design for a picture-frame, substantially as herein shown and described.

85,926. PICTURE-FRAME. HARRY H. GOSLA, Philadelphia, Pa. Filed Feb. 21, 1902. Serial No. 36,133. Term of patent 24 years.

85,926.

Claim.—The design for a picture-frame, as herein shown and described.

85,927. BADGE. JOHN O'CALLAHAN, Philadelphia, Pa. Filed Apr. 12, 1902. Serial No. 33,361. Term of patent 7 years.

Claim.—The design for a badge, substantially as shown and described.

TRADE-MARKS

REGISTERED MAY 27, 1902.

88,821. GAME. COLUMBIAN GAME COMPANY, Norwood, Ohio. Filed Apr. 18, 1902.

LERNALOT

The word "LERNALOT." Used since March 8, 1902.

88,822. GOLF-BALLS. THE "SANTAS" COMPANY, LIMITED, New York, N. Y. Filed Apr. 18, 1902.

FLIPOOT

The word "FLIPOOT." Used since April 9, 1902.

88,823. CERTAIN NAMED FISHING-TACKLE. HENRY MILWARD & SONS, LIMITED, Redditch, England. Filed Apr. 21, 1902.

The figure of a mailed arm holding in the hand a fishhook. Used since 1881.

88,824. CERTAIN NAMED JEWELRY. ARNOLD E. CLOVER CO., Chicago, Ill. Filed Mar. 19, 1902.

The representation of a four-leaf clover, one leaf bearing the letter "A," a second leaf the letter "B," a third leaf the letter "C," and the remaining leaf the letters "CO." Used since February 12, 1902.

88,825. CORSET. WEINSTEIN BROS., New York, N. Y. Filed Apr. 26, 1902.

LaRaso

The words "LA RASO." Used since April, 1901.

88,826. CORSET. BIRDNEY & SCHERER, New York, N. Y. Filed Nov. 26, 1901.

The word "ARMORIDE" in letters of white on a dark background within a rectangular panel, the word extending from the lower left-hand corner of the background to the upper right-hand corner, and above and below the word white scrolls appear, while in the lower right-hand corner a circular figure appears. Used since July, 1893.

88,827. CERTAIN NAMED FABRIC. GRINNELL WILSON, New York, N. Y. Filed Apr. 11, 1902.

The words "DRAGON FLY" and the representation of a dragon-fly and crest pose and a surrounding border. Used since April 1, 1902.

MAY 27, 1902.

U. S. PATENT OFFICE.

2093

88,828. COTTON FABRIC. SHANNON & Co., New York, N. Y. Filed Apr. 26, 1902.

The representation of a crawfish, a spider, and flowers, arranged in Chinese style. Used since August 15, 1901.

88,829. COTTON FABRIC. SHANNON & Co., New York, N. Y. Filed Apr. 26, 1902.

The representation of a monkey on horseback and the limb of a tree with leaves and fruit above the same. Used since August 15, 1901.

88,830. COTTON FABRIC. SHANNON & Co., New York, N. Y. Filed Apr. 26, 1902.

The representation of a limb, leaves, and blossoms of the Sugar-Beet. Used since August 15, 1901.

88,831. YARN. ARNOLD OTTO MEYER, Hamburg, Germany. Filed June 12, 1901.

The pictorial representation of an Indian warrior. Used since September 14, 1882.

88,832. RUBBER FOOTWEAR. FINE, BURLIN & COMPANY, St. Paul, Minn. Filed Mar. 15, 1902.

BURR OAK.

The words "BURR OAK." Used since February 8, 1902.

88,833. LEATHER. HARRY L. RICE, Boston, Mass. Filed Apr. 2, 1902.

The representation of two boxing calves and the word "CHAMPION." Used since November 1, 1901.

88,834. HERRING. GEORGE HOOGSTRAAT, Vlaardingen, Rotterdam. Filed Feb. 4, 1902.

The representation of a banner, with the letters "H. W." thereon, and the word "BANNER." Used since August 6, 1900.

88,885. BUTTER. LUTHERS BROS., New York, N. Y. Filed Apr. 28, 1902.

DAMA

The word "DAMA." Used since April 1, 1899.

88,886. CERTAIN NAMED GROCERY SUNDRIES. AMER. BROS. & CO., New York, N. Y. Filed Feb. 27, 1902.

The representation of a scale, scales upon the end of the scale, an eagle with outspread wings appearing as about to alight on the scale, and a shield in front of the breast of the eagle and bearing a monogram of the letters and character "A M & C." Used since December, 1900.

88,887. CERTAIN NAMED SUGGEST SUPPLIES. J. S. SUGGEST, New York, N. Y. Filed Apr. 4, 1902.

Three Star

Three stars and the words "THREE STAR." Used since September, 1899.

88,888. WITTEDRAWN.

88,889. MEAT EXTRACT, BOUILLON, AND BEEF-TIA. THE CORDON FARMER CO., Chicago, Ill., and South Omaha, Neb. Filed Jan. 2, 1902.

REXONA

The word "REXONA." Used since October, 1901.

88,840. COPPER, MOLASSES, TEAS, AND SPICES. NEW ORLEANS COPPER CO., Ltd., New Orleans, La. Filed May 1, 1902.

CHIEF

The word "CHIEF" and the bust of an Indian chief with full plume head-dress. Used since December 23, 1901.

88,841. PASTE. CHARLES R. FORTY, Alexandria Bay, N. Y. Filed Apr. 24, 1902.

AKOS

The word "AKOS." Used since April 15, 1902.

88,842. SOAP. KEEB BROS. & COMPANY, Chicago, Ill. Filed Apr. 16, 1902.

FEDERAL

The word "FEDERAL." Used since April 12, 1902.

88,843. PERFUMERY, SOAP, AND FACE-POWDER. KAMMAM ABRAM GARDNER, New York, N. Y. Filed Jan. 15, 1902.

The portrait of Joseph Bey Karam, deceased, associated with the name "JOSEPH BEY KARAM." Used since September 16, 1901.

88,844. CHOCOLATE. NEW YORK VICTORIAN MANUFACTURING CO., New York, N. Y. Filed Apr. 15, 1902.

CHULONG

The word "CHULONG." Used since January, 1902.

88,845. CHOCOLATE CHIPS. HONEY COMB CHOCOLATE CHIP CO., Ltd., Baltimore, Md. Filed Apr. 15, 1902.

The words "HONEY COMB" in connection with the representation of a beehive and bees about the same. Used since March 27, 1902.

88,846. CERTAIN NAMED CONFECTIONERY. MRS. L. M. GUTHRIE, New York, N. Y. Filed Apr. 15, 1902.

MIRROR

The word "MIRROR." Used since October 15, 1899.

88,847. CIGARETTES. ARTHUR G. WALKER, New York, N. Y. Filed Apr. 17, 1902.

BIRCH BARK

The words "BIRCH BARK." Used since April 1, 1902.

88,848. REMEDIES FOR CERTAIN NAMED DISEASES. THOMAS H. KENTON, Minneapolis, Minn. Filed Nov. 21, 1901.

A pictorial representation of the head of a little girl enclosed in a circular frame. Used since November 2, 1899.

88,849. INTERNAL REMEDY FOR A CERTAIN NAMED DISEASE. ANNA R. GIBBS, New York, N. Y. Filed Apr. 16, 1902.

Caso-Juo.

The hyphenated word "CASO-JUO." Used since January 24, 1902.

88,850. LA GRIPPE AND KIDNEY CURE. GEORGE R. HAYTHORN, Morgantown, Ky. Filed Apr. 16, 1902.

WORLD'S WONDER

The words "WORLD'S WONDER" in connection with the photograph of the registrant. Used since April 1, 1901.

88,851. MEDICAL COMPOUND FOR SUBCUTANEOUS, SYNECDOLOGICAL AND ORTHODONTIC USE. JAMES FLANNERY GIBBS, New York, N. Y. Filed Mar. 27, 1902.

Luborine

The word "LUBORINE." Used since February 1, 1901.

88,852. EXTERNAL REMEDY FOR SKIN DISEASES. JAMES FLANNERY GIBBS, New York, N. Y. Filed Feb. 15, 1902.

The representation of the naked bust of a man, with the hands crossed on the breast, with the representation of spots on the face, breast and arms to indicate skin diseases. Used since August 11, 1900.

88,853. EXTERNAL REMEDIES. THE ALPINE CHEMICAL COMPANY, New York, N. Y. Filed Apr. 24, 1902.

KAOPLASMA

The word "KAOPLASMA." Used since November 1, 1901.

88,854. LINIMENT. ALBERT G. CHARLTON, Plymouth, Pa. Filed Mar. 13, 1902.

ZMIJECHNIK

The Polish word "ZMIJECHNIK." Used since January, 1903.

88,855. LINIMENT. FRANK SAVALLA, Dayton, Ohio. Filed Jan. 21, 1901.

The portrait of the registrant. Used since April 10, 1900.

88,856. WITHDRAWN.

88,857. SALVE. GEORGE BROWN, Windsor, Ind. Filed Mar. 22, 1902.

The best portrait of Mrs. Anna M. Gross, mother of the registrant, and her autograph, "ANNA M. GROSS." Used since January, 1903.

88,858. LIQUID DISINFECTANTS. FRANK BROOKS BROTHERS CO., New York, N. Y. Filed Feb. 6, 1902.

SAVOMOR

The word "SAVOMOR." Used since December 23, 1901.

88,859. MOSQUITO AND FLY REPELLENTS AND INSECT-EXTERMINATORS. FRANK MANUFACTURING COMPANY, Oshkosh, N. Y. Filed Dec. 2, 1901.

PRESTO

The word "PRESTO." Used since 1901.

88,860. VERMIN-DESTRUCTORS. ALFRED KATHAN, Montreal, Canada. Filed Apr. 22, 1902.

The initials "A K" in white on a black shield, having above and below two sets of curved lines, to the right a representation of a roach to the left a representation of a bedbug, and in the four corners representations of mice or rats. Used since January 1, 1903.

88,861. DOMESTIC DISINFECTANTS. WARREN BROTHERS COMPANY, Boston, Mass. Filed Apr. 7, 1902.

KARBO

CRIOLENE

The word "KARBO-CRIOLENE." Used since March 20, 1902.

88,862. HYDRAULIC COMPOSITION OR CEMENT. WARREN
BROOKMAN COMPANY, Boston, Mass. Filed Apr. 2, 1902.

ASPHAL STONE

The word "ASPHALSTONE." Used since January 1, 1901.

88,863. HYDRAULIC COMPOSITION OR CEMENT. WARREN
BROOKMAN COMPANY, Boston, Mass. Filed Apr. 11, 1902.

STONE BOUND

The word "STONEBOUND." Used since January 1, 1902.

88,864. PAINT FOR GALVANIZED IRON. THE GOSWELL IRON CO.,
Canton, Ohio. Filed Apr. 12, 1902.

Galvanum.

The word "GALVANUM." Used since August 12, 1902.

88,865. LINE, PLASTER, AND CEMENT. THE TOLSON BUILDING
SUPPLY CO., Toledo, Ohio. Filed Apr. 22, 1902.

CRESCENS

The word "CRESCENS" and the representation of a panel showing
a landscape background with a horse in the foreground. Used since
June 1, 1901.

88,866. FOUNTAIN-KEEPING SUPPLIES. CROWN FOUNTAIN
CO., Buffalo, N. Y. Filed Jan. 20, 1902.

A diamond-shaped figure having within it the representation of an
egg and the heads of two chicks. Used since October 5, 1901.

88,867. CARPET-SWEEPER. BARNES CARPET SWEEPER CO.,
Grand Rapids, Mich. Filed Apr. 2, 1902.

Crown Jewel.

The words "CROWN JEWEL." Used since February 17, 1902.

88,868. SEWING-MACHINES AND ATTACHMENTS. WILLIAM
ALLEN CHURCH, New York, N. Y. Filed Apr. 17, 1902.

NIRVANA

The word "NIRVANA." Used since January 20, 1902.

88,869. ELECTRIC SWITCHES. THE EAST MANUFACTURING CO.,
Hartford, Conn. Filed Nov. 22, 1901.

A diamond-shaped figure, within which appears the letter "H."
Used since May, 1900.

88,870. CERTAIN MARKING MACHINES. MARK MARKING TOOL
COMPANY, Springfield, Mass. Filed Mar. 17, 1902.

The representation of the terrestrial globe, on which are represented
longitudinal divisions, across which, centrally between the poles of the
globe, extends an equatorial band. Used since February 1, 1900.

88,871. ROOFING-SLATE. AMERICAN SLATE COMPANY,
Butte, Pa. Filed Mar. 24, 1902.

The representation of a circle the background of which is a solid
red. Used since February 11, 1902.

88,872. ROOFING-SLATE. SEAR SLATE COMPANY, Butte, Pa.
Filed Mar. 24, 1902.

A six-pointed star the background of which is solid red. Used
since February 11, 1902.

DECISIONS

OF THE
COMMISSIONER OF PATENTS
AND OF
UNITED STATES COURTS IN PATENT CASES.

COMMISSIONER'S DECISIONS.

EX PARTE MCCLAIN.

Decided May 7, 1908.

TRADE-MARKS—"Felt-Less"—DESCRIPTIVE.

The word "Felt-Less" as a trade-mark for sweat-pads used in connection with harness for horses refused registration on the ground that it is either descriptive or deceptive.

TRADE-MARK FOR SWEAT-PADS.

Application of Edward L. McClain filed October 23, 1898, No. 56,719.

Messrs. Murray & Murray for the applicant.

ALLEN, Commissioner:

This is an appeal from the action of the Examiner of Trade-Marks in refusing to register the word "Felt-Less" as a trade-mark for sweat-pads.

The pads to which the trade-mark is applied are used in connection with harness for horses. Such pads as commonly made comprise in their construction a thick piece of felt. It is clear, therefore, that the word "Felt-Less" as applied to a sweat-pad for harness would naturally be understood to be a pad made without felt. So understood the word is obviously either descriptive or deceptive and for this reason unregistrable as a trade-mark.

Applicant contends that in the present case the word is not descriptive, because as a matter of fact the pads to which it is applied do have felt upon them in very prominent positions and that for this reason the word would not be taken in a descriptive sense by the purchasing public. Without actual inspection of a pad, however, it would be supposed by an intending purchaser that a pad to which this trade-mark is applied is one containing no felt. The word is therefore descriptive.

Applicant contends, further, that this word is composed of the two words "felt" and "less" and that it is "suggestive of the idea that the pad rests more lightly on the neck of a horse than do other pads on the market. In reply to this it may be said that although it does not so appear in the brief filed by applicant, yet it was stated orally at the hearing that the pads are made of canvas stuffed with hair, the only felt thereon being applied thereto for ornament and not as a wearing-surface. In view of the fact that the pads in ordinary use have, as above noted, a wearing-surface of felt, the argument that the word "Felt-Less"

300 a—4—11

applied to applicant's pads would not be taken in a descriptive sense is not convincing. The decision of the Examiner of Trade-Marks was correct, and it is accordingly affirmed.

EX PARTE FIEBEGGER.

Decided May 8, 1907.

TRADE-MARK—"Solid Comfort" FOR FURNACES—NOT DESCRIPTIVE—REGISTERABLE.

The words "Solid Comfort" held to be registrable as a trade-mark for furnaces on the ground that even though these words may convey the idea that persons using these furnaces will experience that degree of comfort known as "solid comfort" they are not descriptive of the quality or construction of the furnaces. They merely suggest a remote result which may be brought about by the use of the furnaces.

ON appeal.

TRADE-MARK FOR FURNACES.

Application of Frank Fiebegger filed October 24, 1901, No. 64,847.

Messrs. Humphrey & Humphrey for the applicant.

ALLEN, Commissioner:

This is an appeal from the refusal of the Examiner of Trade-Marks to register the words "Solid Comfort" as a trade-mark for soft-coal furnaces.

The Examiner holds that these words are "manifestly descriptive and advertising as applied to soft-coal furnaces."

The words "Solid Comfort," even though they may convey the idea that persons using these furnaces will experience that degree of comfort known as "solid comfort," are not descriptive of the quality or construction of the furnaces. The words merely suggest a remote result which may be brought about by the use of the furnaces, and for this reason they are registrable. (*O'Rourke v. Central City Soap Company*, 35 O. G., 875.)

As stated in *ex parte Peek*, (96 O. G., 425:)

The result or condition suggested by the word is so remote from the article to which it is applied that it cannot be held to be one of those descriptive terms which any person has the right to use in describing similar articles and which therefore cannot be exclusively appropriated by one person.

The decision of the Examiner of Trade-Marks is reversed.

EX PARTE SACK.

Decided May 12, 1908.

ABANDONED APPLICATION—INSUFFICIENT ACTION.

Where the Examiner called attention to a formal defect in the application and the applicant while admitting the defect made no effort for six years to correct it, but merely wrote letters in regard to it, held that the application is abandoned.

3101

ON petition.

PHOTOGRAPHIC-PRINTING FRANK.

Application of Hugo Sack filed June 10, 1896, No. 505,006.

Mr. Francis M. Wright for the applicant.

ALLEN, Commissioner:

This is a petition from the action of the Primary Examiner holding that the above-entitled case is abandoned.

In his first letter in this case, dated July 13, 1896, the Examiner said that the oath was informal in that the seal of the notary was omitted and required a new oath. None of the claims was rejected, and this was the only requirement made. On July 13, 1896, the attorney filed a request for reconsideration, saying that the informality in the oath could be cured as well by furnishing evidence of the official character of the notary. He made no effort, however, to correct the informality by furnishing evidence of the official character of the notary, as suggested by him, or by furnishing a new oath, as suggested by the Examiner, and therefore the Examiner wrote him on July 18, 1896, that the case was abandoned. On June 4, 1900, the applicant requested reconsideration of the holding that the case was abandoned and on April 11, 1902, filed this petition from that holding.

It is apparent from this statement of the case that nearly six years ago the applicant was notified of a simple formal defect in the application and that he has not during all of that time made any effort whatever to correct it. It is clear that the actions of the applicant were not such proper actions as the condition of the case required. (Rule 171.) The defect was admitted and no effort was made to correct it, and it therefore appears that the purpose was merely to delay the case in this Office.

The petition is denied.

DECISIONS OF THE U. S. COURTS.

Supreme Court of the United States.

THE EXCELSIOR WOODEN PIPE COMPANY v. THE PACIFIC BRIDGE COMPANY *et al.*

Decided May 5, 1902.

1. JURISDICTION OF FEDERAL COURTS—QUESTION UNDER PATENT LAWS—CONTRACT—INFRINGEMENT.

Where the defendant gave to the complainant an exclusive license under his patent and subsequently gave a license to a third party in the same territory, alleging that the first license is void for failure to comply with its terms, *Held* that a bill to recover damages for infringement and for an injunction raises a question under the patent laws which is within the jurisdiction of the United States courts and is not merely a question of contract.

2. SAME—SAME—RIGHT UNDER PATENT.

To constitute an action arising under the patent laws of the United States, the plaintiff must set up some right, title, or interest under the patent laws, or at least make it appear that some right or privilege will be defeated by one construction or sustained by the opposite construction of those laws.

[Vol. 99. No. 9.]

3. SAME—SAME—REMEDY IN STATE COURT INADEQUATE.

Before it can be held that the allegations of the bill oust the jurisdiction of the United States court it must at least appear that the plaintiff has another remedy by an action in a State court, and where an action in that court would be inadequate or would involve questions under the patent law jurisdiction of the United States court is not ousted.

4. SAME—SAME—REMEDY FOR INFRINGEMENT.

Where the only remedy which an alleged licensee had against a violation of his license by the patentee was to prosecute the patentee as an infringer of his rights under the patent, *Held* that the question is one arising under the patent laws and is within the jurisdiction of the United States courts.

5. SAME—CONTRACT CONCERNING PATENTS—SUIT FOR INFRINGEMENT.

The jurisdiction of the Federal courts cannot be invoked primarily for the determination of the rights of parties to a contract concerning patents; yet when the bill is an ordinary one for infringement and the answer puts in issue the title of the plaintiff to sue the jurisdiction is not ousted by the mere allegation that the license has been revoked.

6. SAME—CASE DISMISSED ON MOTION OF COURT.

It is the duty of the circuit court on its own motion to dismiss the case whenever at any time it shall appear that its jurisdiction has been improperly invoked.

7. APPEAL TO SUPREME COURT FROM CIRCUIT COURT—QUESTION OF JURISDICTION.

On an appeal directly to the Supreme Court from a decision of the circuit court it must appear either that the question of jurisdiction was certified or that the decree appealed from shows upon its face that the sole question decided was one of jurisdiction. A statement to that effect in allowing an appeal is, however, a sufficient certificate that the question is one of jurisdiction.

On appeal from the Circuit Court of the United States for the District of Washington.

STATEMENT OF THE CASE.

This was a bill in equity filed by the Excelsior Wooden Pipe Company, a California corporation, against the Pacific Bridge Company, also a California corporation, but having a branch in the city of Seattle, Wash., and Charles P. Allen, for the infringement of a patent issued to Allen, one of the defendants, for a wooden pipe.

Besides the usual allegations of a bill for the infringement of a patent, the plaintiff averred that, prior to the acts charged against the respondents, the said Charles P. Allen, one of the defendants, had granted December 20, 1892, unto the Excelsior Redwood Company, a California corporation, the exclusive right within the Pacific States of manufacturing and selling wooden pipe under his patent to the full end of its term; that the Excelsior Redwood Company had, with the written consent of Allen, the patentee, on December 22, 1892, transferred unto the Excelsior Wooden Pipe Company, plaintiff, the said exclusive license to it, from Allen, with all rights and privileges thereunder, and that Allen had been, and still was, the exclusive owner of the patent, and the plaintiff the sole and exclusive licensee; that the plaintiff has ever since and still is engaged in the manufacture and sale of the patented articles, and has filled all orders therefor, and is well known as the exclusive licensee, and that Allen has joined with the plaintiff in suits against infringers of his patent, all of which have resulted in his favor. The gravamen of the bill lies in the allegation that, notwithstanding all this, the defendant, the Pacific Bridge Company, and the said Allen, have since such license conspired to make and sell, and without the license and consent of your orator, extensive licenses as aforesaid, have made and sold, within one year last past, within the State of Washington, wooden pipe substantially the same as that described in the patent and embodying the invention; and therefore it brought this bill to recover damages for this infringement and for an injunction.

[Vol. 99. No. 9.]

The answer, which was a joint one of both defendants, admitted the issue and validity of the patent and its ownership by defendant Allen. It is also admitted a license by defendant Allen to plaintiff's assignor, whereby the latter obtained the exclusive right to make and sell the patented articles in the territory described, and set out the license in full; but it denied that this license was a subsisting one, and alleged an abandonment of the same by the plaintiff, a forfeiture of all rights thereunder by failure and refusal to comply with its terms and conditions, and by acts of bad faith toward the patentee by seeking to defeat the patent and destroy its monopoly; and a revocation of the license by Allen for cause in pursuance of the terms of the contract. It also set up that after the alleged revocation of the license the defendant Allen granted a license to his joint defendant, the Pacific Bridge Company. In short, the only defense was a denial of the license which lies at the basis of plaintiff's suit, and constitutes its title to the patent.

The usual replication was filed, and, pending an application on the part of defendants for an extension of time to take proofs, the plaintiff, apparently at the suggestion of the court, moved for a decree in its favor upon the pleadings and affidavits on file. Upon argument, which was upon the question of jurisdiction alone, the court held that the suit was not one arising under the patent laws, but solely out of a contract; that the court had no jurisdiction, and a decree was entered to that effect. Plaintiff thereupon appealed to the circuit court of appeals, which dismissed the case upon the ground that it had no jurisdiction itself over the appeal, and that, as such appeal was prosecuted from an order dismissing the bill solely for want of jurisdiction, it should have been taken to this Court. (109 Fed. Rep., 497.) Whereupon the mandate of the circuit court of appeals being filed in the circuit court, an appeal from the final decree of that court, which had been entered November 5, 1900, was taken to this Court.

Mr. Nicholas A. Acker, Mr. L. S. Bacon, and Mr. W. W. Wilshire for the appellant.

Mr. James B. Howe for the appellee.

Mr. Justice Brown delivered the opinion of the Court.

1. Motion is made by defendants to dismiss this appeal upon the ground that no appeal was taken, and no certificate of the trial court upon the question of jurisdiction, was made by such court during the term at which the decree was rendered; and that no such certificate has since or ever been made.

As the appeal was taken directly to this Court, it must appear, under the fifth section of the Court of Appeals act, either that the question of jurisdiction was certified to this Court, or that the decree appealed from shows upon its face that the sole question decided was one of jurisdiction. Plaintiff evidently supposed that the case was a proper one to carry to the court of appeals, but its appeal having been there dismissed, it took this appeal May 27, 1901, from the original decree of the circuit court made November 5, 1900. This decree, after reciting—

that said suit does not really and substantially involve a dispute or controversy properly within the jurisdiction of this court, and that this court should not further exercise jurisdiction, it is therefore ordered and decreed that said suit be and the same is hereby dismissed for want of jurisdiction.

An appeal was taken from this decree, and the order allowing the appeal states that the appeal was allowed—

[Vol. 99. No. 9.]

from the final order and decree dismissing said suit for want of jurisdiction.

This is clearly a sufficient certificate of the circuit court that the jurisdiction of that court was in issue, and the only question to be considered by us relates to the jurisdiction of that court. (*Shields v. Coleman*, 157 U. S., 168; *in re Lehigh Mining Co.*, 156 U. S., 322; *Huntington v. Laidley*, 176 U. S., 668.)

The case, being thus in proper condition for appeal, such appeal could be taken at any time within two years. (*Allen v. Southern Pacific R. R. Co.*, 173 U. S., 479; *Holt v. Indiana Manfg. Co.*, 176 U. S., 68.)

2. The most important question is whether this is a suit under the patent laws of the United States within the meaning of Revised Statutes sec. 629, sub. 9, which grants original jurisdiction to the circuit courts—

of all suits at law or in equity arising under the patent or copyright laws of the United States.

The rule is well settled that, if the suit be brought to enforce or set aside a contract, though such contract be connected with a patent, it is not a suit under the patent laws, and jurisdiction of the circuit court can only be maintained upon the ground of diversity of citizenship. But difficulties sometimes arise in determining whether the action be upon a contract or upon the patent. The first case involving this question was *Wilson v. Sandford*, (10 How., 99,) in which a bill filed on the equity side of the circuit court by the assignee of a patentee, to set aside a contract in the nature of a license upon the ground that the licensee had not complied with the terms of the contract, was held not to be a case under the patent laws. The object of the bill was to have the license set aside and forfeited, and plaintiff's title reinvested in him. Such was also the case in *Brown v. Shannon*, (20 How., 55,) which was a bill to enforce the specific execution of certain contracts respecting the use of the patent; and in *Albright v. Teas*, (23 O. G., 2099; 106 U. S., 618,) which was a suit brought by the plaintiff for moneys alleged to be due under a contract whereby certain Letters Patent granted to him were transferred to the defendant. This was clearly a bill to recover royalties, and no question under the patent laws was involved. *Dale Tile Manfg. Co. v. Hyatt* (43 O. G., 249; 125 U. S., 46) was an action in a State court by the owner of the patent upon an agreement by which such owner granted an exclusive license to make and sell the patented articles within a certain territory. Defendant expressly acknowledged the validity of the patent. This, we held to be, clearly within the jurisdiction of the State court. A like ruling was made in the next case of *Feltz v. Scharnweber*, (43 O. G., 351; 125 U. S., 54.) In the same line of cases are those of *Marsh v. Nichols*, (56 O. G., 359; 140 U. S., 844,) to enforce the specific performance of a contract to transfer an interest in a patent to the plaintiff; *Wade v. Lawder*, (165 U. S., 634;) and *Pratt v. Paris Light & Coke Co.*, (168 U. S., 355,) which was an action by patentees in a State court upon the common counts to recover of

the defendant the stipulated price for manufacturing and setting up an apparatus for the manufacture of water-gas. Defendant pleaded that the plaintiff had agreed to save it harmless against any suit which might be brought against it for infringement, and to defend such suits at their own expense, and averred, among other things, that the patents were void and an infringement upon prior patents; that defendant had not kept plaintiffs harmless against such suits, but had refused to defend a certain suit brought against it, and that the defendant had rightfully rescinded the contract. It was held that the action was not one arising under the patent laws of the United States, and that to constitute such a cause the plaintiff must set up some right, title or interest under the patent laws, or at least make it appear that some right or privilege will be defeated by one construction or sustained by the opposite construction of those laws. That—

section 711 does not deprive the State courts of the power to determine questions arising under the patent laws, but only of assuming jurisdiction of cases arising under those laws. There is a complete distinction between a case and a question arising under the patent laws. The former arises when the plaintiff in his opening pleading—be it a bill, complaint or declaration—sets up a right under the patent laws as ground for a recovery. Of such the State courts have no jurisdiction. The latter may appear in the plea or answer or in the testimony. The determination of such question is not beyond the competency of the State tribunals.

Now, as the bill in this case differs from an ordinary bill for infringement only in the fact that the suit is by a licensee against two defendants, one of whom is the licensor and owner of the patent, and the license is set forth only for the purpose of showing title, there would be no difficulty whatever in sustaining it, were it not for the question whether we are not also bound to consider the averments of the answer. We think this difficulty is practically settled by a reference to section 5 of the Jurisdictional Statute of 1875, (18 Stat., 470, 472,) which provides—

that if, in any suit commenced in a circuit court, . . . it shall appear to the satisfaction of the said circuit court, at any time after such suit has been brought, . . . that such suit does not really and substantially involve a dispute or controversy properly within the jurisdiction of said circuit court, . . . the said circuit court shall proceed no further therein, but shall dismiss the suit, &c.

While it seems reasonable to say that a jurisdiction once acquired by the filing of a proper bill ought not to be taken away by any subsequent pleading, the statute is peremptory in this particular, and requires the court to dismiss the case whenever at any time it shall appear that its jurisdiction has been improperly invoked. We are by no means without authority upon this question. In *Robinson v. Anderson* (121 U. S., 523) it was held that when it appeared, after all the pleadings were filed, that the averments in the declaration which alone gave the court jurisdiction, were immaterial and made for the purpose of creating a case cognizable by the court, it was the duty of the circuit court to dismiss the bill for want of jurisdiction. Said the Chief Justice:

Even if the complaint, standing by itself, made out a case of jurisdiction, which we do not decide, it was taken away as soon as the answers were in, because if there was jurisdiction at all it was by reason of the averments in the complaint as to what the defenses against the title of the plaintiff would be, and these were of no avail as soon as the answers were filed and it was made to appear that no such defenses were relied on.

[Vol. 99, No. 9.]

In *Williams v. Nottawa* (104 U. S., 200) this Court went so far as to dismiss a case in which judgment had been rendered for the plaintiff in the circuit court, because it appeared from the testimony of the plaintiff that certain bonds were put in his hands for collection in which he had no real interest. It was held that it was the duty of the circuit court on its own motion, as soon as the evidence was in and the collusive character of the case shown, to stop all further proceedings and dismiss the suit, the Chief Justice further remarking that this provision of the act of 1875 was a salutary one, and that it was the duty of the circuit courts to exercise their power under it in proper cases. See also *Wetmore v. Rymer*, (160 U. S., 115;) *Morris v. Gilmer*, (129 U. S., 315;) *Lake County Commissioners v. Dudley*, (173 U. S., 243.)

Is there anything in the answer to show that the court was bound to dismiss the bill for want of jurisdiction?

The bill makes the usual allegations of a bill for infringement, and puts in issue (1) the title of the plaintiff, which in this case was a license from one of the defendants, fully set forth in the margin;* (2) the validity of the patent; and (3) the infringement. The answer raises no issue as to the validity of the patent, or as to the acts charging infringement. It admits the license, but denies that it is a subsisting one, and pleads abandonment of the same by plaintiff, a forfeiture of all rights thereunder by failure to comply with its terms and conditions, and by acts of gross bad faith toward the

* *License and agreement.*—This agreement, made this 11th day of March, 1898, by and between Charles F. Allen, of Denver, Colo., party of the first part, and the Excelsior Redwood Company, a corporation duly organized and existing under and by virtue of the laws of the State of California, and having its principal place of business in the city and county of San Francisco in said State, party of the second part:

Witnesseth: That, whereas, the party of the first part is the owner and holder, for, to and in the States and Territories hereinafter mentioned, of the whole right, title and interest in and to Letters Patent of the United States, No. 589,590, dated March 28, 1897, for "wooden pipe."

And, whereas, the party of the second part is desirous of obtaining for, to and within the said States and Territories hereinafter mentioned an exclusive right, license and privilege to manufacture and sell wooden pipe under and in accordance with said Letters Patent:

Now, therefore, the parties have agreed as follows: The party of the first part hereby grants, subject to the conditions hereinafter stated, unto the party of the second part, its successors and assigns, the exclusive right, license and privilege, within the States of Northern California, Oregon, Washington, Nevada, Montana and Idaho, and Territories of Arizona and Utah, of manufacturing and selling wooden pipe under and in accordance with the said Letters Patent, to the full end of the term of said Letters Patent.

The party of the second part agrees to pay unto the party of the first part, as a license fee or royalty under this license and agreement, the following sums to wit: One dollar (\$1.00) on every one thousand feet, board measure, of lumber employed in the manufacture of said pipe, and two and one-half per cent. (2½%) on the cost at factory of all steel and iron used in said manufacture.

The said license or royalty is to be paid by the said party of the second part to the said party of the first part upon the final payment to the party of the second part of the contract price on each and every contract taken by said party of the second part, involving the manufacture and sale of said patented wooden pipe. The right, license and privilege hereby granted is not transferable or assignable, either in whole or part, by the party of the second part, without the consent of the party of the first part. It is agreed that in case the party of the second part shall fail to use the above-described patent in any pipe constructed by them, of twelve (12) inches diameter and upward, or from any cause the said party of the second part shall cease the manufacture of wooden pipe, then and in that event all the rights and privileges granted by this agreement and license to the said party of the second part shall at once be revoked.

It is understood and agreed that this agreement is binding upon the heirs, legal representatives and assigns of the party of the first part, and upon the successors and assigns of the party of the second part.

patentee by seeking to defeat the patent, and a revocation of the license by Allen. It will be observed that the answer raises no question of the construction of the license, but merely of its existence—that is, of the title of the plaintiff to sue. Before deciding that these allegations oust the jurisdiction of the court it must at least appear that the plaintiff has another remedy by an action in a State court. But what remedy has it? All the agreements and conditions of the license are such as are made by the plaintiff's assignor, the Excelsior Redwood Company. This company, the party of the second part, agrees first, to pay a license fee or royalty, the time of payment being fixed in a subsequent sentence; second, that it will neither transfer nor assign the license without the consent of the patentee, (it was admitted that the patentee consented to the assignment to plaintiff;) third, that in case the licensee should fail to use the patent in any pipe constructed by them, or from any cause it should cease to manufacture a wooden pipe, the license shall be at once revoked. The only clause in the license in which the patentee appears as promisor is that wherein—

he hereby grants, subject to the conditions hereinafter stated, unto the party of the second part, its successors and assigns, the exclusive right, license and privilege within—
certain States—

of manufacturing and selling wooden pipe under and in accordance with the said Letters Patent to the full end of the term of said Letters Patent.

Now, it may be freely conceded that, if the licensee had failed to observe any one of the three conditions of the license, the licensor would have been obliged to resort to the State courts either to recover the royalties, or to procure a revocation of the license. Such suit would not involve any question under the patent law.

But the same does not hold good with respect to the licensee. There were practically but two ways in which the patentee could impair the grant he made to the licensee, and those were by a revocation of the license by a bill in equity, or by treating it as abandoned and revoked, and granting a license to another party. He elected the latter remedy, and made a contract with the Pacific Bridge Company to make and sell wooden pipe within the same territory. A suit in a State court would either be inadequate or would involve questions under the patent law. If the licensee sued at law he would be obliged to establish the fact that the patent had been infringed, which the patentee might have denied, and in any case could only recover damages for past infringements. If he sued in equity, he could only pray an injunction against future infringements; but this is exactly what he prays in this case, and thereby raises a question under the patent laws. In either case the patentee could defeat the action by showing that he did not infringe,—in either case the defendant could so frame his answer as to put in issue the title, the validity or the infringement of the patent.

The natural and practically the only remedy, as it seems to us, was for the plaintiff to assert his title under the license and to prosecute the defendants as infringers. In doing this he does what

[Vol. 99,

every plaintiff is bound to do, namely, set forth his title either as patentee, assignee or licensee, and thereby puts that title in issue. The defendant is at liberty in such a case to deny the title of the plaintiff by declaring that the license no longer exists, but in our opinion this does not make it a suit upon the license or contract, but it still remains a suit for the infringement of a patent, the only question being as to the validity of plaintiff's title. There can be no doubt whatever that if the plaintiff sued some third person for an infringement of his patent, the defendant might attack the validity of his license in the same way, but it would not oust the jurisdiction of the court. Why should it do so in this case?

Much reliance is placed upon the case of *Hartell v. Tighman*, (99 U. S., 547,) which was a bill by a patentee against one with whom he had made a contract in the nature of a license, alleging that defendants, after paying the royalty for several months, refused to do certain other things which he charged to have been a part of the contract, and thereupon he forbade them further to use his patented process, and charged them as infringers. Defendants pleaded the contract as they understood it, and the tender of all that was due plaintiff under it, and their readiness to perform it.

Plaintiff's case was that there was a verbal agreement that he should prepare and put up his patented mechanism in defendants' workshop, and that after this was done defendants should take a license for the use of the invention. The machinery was put up, but defendants refused to sign the license apparently upon the ground that the patentee claimed the right to visit the works of the defendants, and inspect their books with a view to ascertaining the amount of work done. The dispute was as to the terms of the agreement, defendants insisting that they had never proposed to accept the license with the conditions mentioned. It was held that the patentee could not sue the defendants for an infringement, and in answer to the objection that he had no other remedy Mr. Justice Miller observed that he could establish his royalty once every year, and sue at law and recover every month or every year for what was due, and that, if he desired to assert his right of examining the works of the defendants, he could in a proper case compel them to submit to the examination. The case is the converse of the one under consideration, inasmuch as it was a suit by the patentee against the licensee for a violation of his contract, and, as the Court observed, the plaintiff might have brought suit for royalties. As already said, the patentee might have done the same in this case, if he had sought to enforce his contract.

Much more nearly analogous to the case under consideration and practically upon all fours with it is that of *Littlefield v. Perry*, (7 O. G., 934; 21 Wall., 305.) This was a suit by an assignee against the patentee, who had made a conveyance to the plaintiff of his patent with all improvements thereon, within certain States, for which plaintiff had agreed to pay royalty upon all articles sold, with a

No. 9.]

clause of forfeiture in case of non-payment or neglect after due notice, to make and sell the patented articles to the extent of a reasonable demand therefor. There was by a supplementary document an agreement reserving to the patentee the right to apply the principle of his invention to one special purpose. It was held that whether the plaintiff was an assignee or a licensee, he had a right to maintain a suit for infringement in his own name in a Federal court against the patentee. Said the Chief Justice:

They [the plaintiffs] certainly had the exclusive right to the use of the patent for certain purposes within their territory. They thus held a right under the patent. The claim is that this right has been infringed. To determine the suit, therefore, it is necessary to inquire whether there has been an infringement, and that involves a construction of the patents, * * * such a suit may involve the construction of a contract as well as of a patent, but that will not out of the court of its jurisdiction. If a patent is involved, it carries with it the whole case.

Upon the subject of a licensee suing his own patentee the Chief Justice observed:

A mere licensee cannot sue strangers who infringe. In such cases redress is obtained through or in the name of the patentee or his assignee. Here, however, the patentee is the infringer, and, as he cannot sue himself, the licensee is powerless, so far as the courts of the United States are concerned, unless he can sue in his own name. A court of equity looks to the substance rather than form. When it has jurisdiction of parties it grants the appropriate relief without regard to whether they come as plaintiff or defendant. In this case the person who should have protected the plaintiff against all infringements has become himself the infringer.

White v. Rankin (59 O. G., 1606; 144 U. S., 628) was a bill by a patentee for infringement, to which there was answer setting up an agreement between the plaintiff and one of the defendants to assign to him an interest in the patent on certain conditions, which it was alleged were performed, and certain other matters which it was alleged gave the defendants the right to make, use and sell the patented invention. The case was tried upon a stipulation admitting that defendants had made and sold the patented inventions, and that a certain written agreement between the plaintiff and one of the defendants had been made as above stated. The circuit court entered a decree dismissing the bill, which was reversed by this Court.

It [the court] appears [said Mr. Justice Blatchford] to have dismissed the bill on the simple ground that the defendant set up a contract of license from White. The bill being purely a bill for infringement, founded upon patents, what was set up by the defendants was set up as a defense and as showing the lawful right in them to do what they had done, and as a ground for the dismissal of the bill because they had not infringed the patents.

The decree was not one upon the facts of the case, but was simply a decree that the Court had no jurisdiction to try the case. The subject-matter of the action, as set forth in the bill, gave the court jurisdiction, and exclusive jurisdiction, to try it. All of the parties to the suit were citizens of California, and if jurisdiction did not exist under the patent laws it did not exist at all.

The circuit court found nothing as to the existence or validity of the contract, decree or deed mentioned in the stipulation. The stipulation provides that at the hearing the contract, complaint, answer, decree and deed set forth in the stipulation may be offered in evidence, subject to such objections as might be urged against the originals thereof. The stipulation further states that the defendants do not admit that anything is due to the plaintiff from Thompson, and that they do admit that nothing had been paid by Thompson to the plaintiff under the decree of the State court of August 28, 1894, and since the making thereof. All these matters and questions ought to have been adjudicated by the circuit court before it could find ground to determine whether or not it should dismiss the bill. Until it had so adjudicated those questions the decision in the case of *Hartell v. Trighman* could not apply.

The cases in the circuit courts and courts of appeal are too numerous to be analyzed, or even cited. One of the most recent and satisfactory is that of the *Atherton Machine Co. v. Atwood-Morrison Co.*, (103 Fed. Rep., 949,) in which it was broadly held that a suit in which the relief sought is an injunction and a recovery of damages for the infringement of a patent is one arising under the patent laws of the United States, although it incidentally involves a determination of the question of the ownership of the patent, which was claimed by both complainant and defendant under separate assignments from the patentee. All the cases cited herein are reviewed and the jurisdiction sustained.

The difficulty with the defendant's position in the case under consideration is that it apparently leaves the plaintiff without an adequate remedy. Defendant has broken no express covenant of the contract, since it has made no covenant. It has simply ignored the existence of the contract and granted a license to another party. It is difficult to see what remedy is available to the plaintiff in a State court that would not involve the right of the defendant to use the patent. In other words, it would be an ordinary suit for infringement in which the Federal courts would alone have jurisdiction. Whether it sued at law or in equity, its damages would be such as are usual in cases of infringement, and the only injunction it could obtain would be against the further use of the invention.

In any suit that could be brought the title of the plaintiff to sue must be put in issue, and, that being the title to the patent, is put in issue in every suit for infringement. We held in *Pratt v. Paris Light & Coke Co.*, (108 U. S., 255,) with respect to an action in a State court, which involved the question whether the patents were void and an infringement upon prior patents, that this did not necessarily oust the State court of its jurisdiction; and by parity of reasoning we hold in this case that the mere fact that the suit may involve the existence of the license does not oust the court of jurisdiction of a suit for the infringement of a patent.

While we do not intend to allow the jurisdiction of the Federal courts to be invoked primarily for the determination of the respective rights of parties to a contract concerning patents, yet when the bill is an ordinary one for an infringement and the answer puts in issue the title of the plaintiff to sue, we think the jurisdiction is not ousted by the mere allegation that the license has been revoked and that the court is at liberty to go on and determine that fact. We regard this question as conclusively settled in *Perry v. Littlefield*, (31 Wall., 205,) and *White v. Rankin*, (144 U. S., 628,) and have no disposition to disturb it.

The decree of the circuit court is, therefore, reversed, and the case remanded to that court for further proceedings consistent with this opinion.

Mr. Justice GRAY did not sit in this case or participate in the decision.

Regulations in Relation to Mail-Matter.

In order to insure the ready identification of the division from which mail-matter emanating from this Office was sent, and the prepayment of any foreign postage thereon, as well as to prevent the retention for general delivery in the post-office of the city of any wrongly-addressed letter when this Office could supply a fuller or more accurate address, it is directed that the following regulations be observed with reference to all mail-matter forwarded from this Office:

Each envelope forwarded from any division will be stamped or marked in the upper left-hand corner with the division number or letter, as the case may be.

Each envelope addressed to a foreign country must be forwarded to the mail-room and the proper stamps affixed thereto before mailing.

Such mail as is to be delivered in this city shall be directed "Washington, D. C." If a letter addressed to a person in this city and not marked for general delivery be returned to this Office, it will be promptly remailed with an accurate and full local address supplied, if possible. In remailing, the envelope should be marked or stamped "Hold in General Delivery," but no envelope should be thus marked until the address thereon is as full and accurate as the Office can supply. A letter to a person in this city will not be filed "Undelivered," until it is returned to this Office in an envelope thus addressed and marked.

Hearings.

DEPARTMENT OF THE INTERIOR,
UNITED STATES PATENT OFFICE,

Washington, D. C., May 18, 1902.

Notice is hereby given that there will be no cases placed upon the docket to be heard by either the Commissioner or the Assistant Commissioner during the months of July and August, 1902.

F. I. ALLEN,
Commissioner.

5. Separate letters must be written about assignments for record, final fees for patents, orders for copies, abstracts of title, complaints against officials, and every other distinct subject of communication.

Publishers' Catalogues.

This Office would be pleased to receive from manufacturers and publishers such catalogues, circulars, price-lists, or other advertisements relating to the sciences and mechanical arts as are published by them for gratuitous distribution; but notice is hereby given such manufacturers or dealers who feel disposed to send their publications that not less than three copies should be forwarded in order that the subjects may be properly indexed, classified, and subclassified in the Scientific Library for convenient and ready reference.

PATENTS

GRANTED JUNE 8, 1902.

701,277. ROPE-FASTENER. FRANK B. ADAMS, Plymouth, Mich.
Filed Oct. 12, 1891. Serial No. 73,944. (No model.)

Claim.—1. A fastener for ropes, &c., comprising a plain oval loop, when viewed from above, said loop being bent on its longer axis into crescent shape, when viewed from the side, to form two similar opposite curved members, and the opposite sides of the loop being connected on its shorter axis by a cross-bar, and a retainer for said cross-bar holding the convex side of the loop next to the support, substantially as set forth.

2. In a rope-fastener, the combination of a plain oval-shaped loop, when viewed from above, bent on its longer axis into crescent shape, when viewed from the side, and forming two similar opposite curved members; the opposite sides of the loop being centrally connected on its shorter axis by a cross-bar; with a retainer engaging said cross-bar and holding the convex side of the loop to the support while permitting rocking of the loop, substantially as described.

3. The herein-described fastener for ropes, &c., comprising a long oval loop when viewed from above, said loop being bent on its longitudinal axis into crescent shape, when viewed from the side, forming two opposite curved members A, B, each side piece of the loop having a central lug, said lugs being connected by a transverse bar; and a retainer lying longitudinally of the loop and athwart said bar, whereby the fastener is permitted a longitudinal rocking movement, substantially as and for the purpose set forth.

701,278. WALL-PAPER CLEANER. WILLIAM ABBOTT, Akron, Ohio, assignor of one-half to John Lee, Akron, Ohio. Filed Aug. 20, 1891. Serial No. 73,570. (No model.)

Claim.—1. A rubber wall-paper cleaner comprising a sponge-rubber portion split lengthwise at its rear and outer and having an inclined working surface, a two-part holder for said rubber constructed to clamp thereon, and a spreader located in the base of said split and adapted to spread the rubber in the holder, and arrows to temporarily lock the sides of the holder together, whereby the rubber can be removed and replaced, substantially as described.

2. The holder consisting of two clamping side sections A and B having a union channel lengthwise within their lower edge, and arrows to clamp them together, in combination with a rubber strip having its edge extending into said channel and split lengthwise at its center, a spreader for the rubber lengthwise through the said split within said channel, the said rubber having an inclined working surface C and the said holder having a rigid bearing portion D forming a backing for said working surface, substantially as described.

701,279. VEHICLE-WHEEL AND TIRE THEREFOR. LOUIS F. ALPHEUS and ROBERT G. ALPHEUS, Chicago, Ill. Filed Nov. 12, 1891. Serial No. 68,061. (No model.)

Claim.—1. In a tire for vehicle-wheels, in combination, a rim having cavities in the periphery thereof, tufts of bristles coated in the cavities and disposed radially as to the wheel, and a covering of rubber filling the interior of and covering the tufts and forming the body of the tire.

2. In a tire for vehicle-wheels, in combination, a rim having cavities in the periphery thereof, tufts of bristles coated in the cavities and disposed radially as to the wheel, a covering of rubber filling the interior of and covering the tufts and forming the body of the tire, a jacket covering the rubber body, and a pair of annular clamps and fastening means therefor for securing the jacket to the wheel-rim.

701,280. ELECTRIC METER. EUGENIUS ARON, Charlestown, Germany. Filed Feb. 20, 1892. Serial No. 64,868. (No model.)

Claim.—1. In an electric meter, the combination with a driving-shaft; of a planet-wheel gearing connected with said driving-shaft; a clock-train to actuate the registering device driven by one of the crown-wheels of said planet-wheel gearing; and a cut-out shaft to open and close the circuit driven by the other crown-wheel of said planet-wheel gearing.

2. In an electric meter, the combination with a driving-shaft; of a planet-wheel gearing connected with said driving-shaft; a clock-train to actuate the registering device driven by one of the crown-wheels of said planet-wheel gearing; a cut-out shaft to open and close the circuit driven by the other crown-wheel of said planet-wheel gearing; a second planet-wheel gearing having one crown-wheel driven by said clock-train; and connections between the other crown-wheel of said last-named planet-wheel gearing and the said cut-out shaft, whereby the movements of said shaft are controlled by said crown-wheel.

701,281. PAPER-HOLDER. JAMES S. BROWN, Wilmington, Del., assignor to E. K. Thompson & Company, Wilmington, Del. Filed Aug. 20, 1891. Serial No. 73,738. (No model.)

Claim.—An improved article of manufacture, a paper-holder formed of a single piece of wire, one end of the same being bent so as to form the two eyelets B at the lower end, the wire then extending upward and being bent so as to form the circle F at the upper end, the wire between the circle and the eyelets adapted to normally lie against the surface to which it is secured, said wire being bent outward and then back just below the circular portion to form a thumb-hold, said wire also being

outward and then back just above the eyelets in form a spring portion, the circular portion being slightly curved outward so that the upper and will normally be at a distance from the surface in which the latter is secured, substantially as and for the purpose set forth.

701,982. INTERCOMMUNICATING TELEPHONE-SWITCH. H. SHAN RANNEY, Philadelphia, Pa., and WILLIAM A. FROST, Camden, N. J., assignors of one-half to Louis Ryerson, Jr. Filed June 10, 1901. Serial No. 94,954. (No model.)

Claim.—1. An intercommunicating telephone-switch comprising a transmitter-base having therein a rigid insulating-plate and electrical connections therein, with plugs operating through said plate and means for simultaneously returning all plugs to their normal positions, as set forth.

2. An intercommunicating telephone-switch, comprising a transmitter-base having therein a fixed horizontal insulating-plate to receive all the electrical connections and intercommunicating plugs, a disk below said plate, a hinged receiver-hook having mechanical connections with said disk, and a spring for depressing said disk, as set forth.

3. An intercommunicating telephone-switch, comprising a transmitter-base, and a hinged receiver-hook, a disk with said base in connection with the receiver-hook, a series of switch-plugs in operative relation with said disk, and means whereby said plugs are locked in position when the disk is elevated by the receiver-hook, as set forth.

4. In an intercommunicating telephone-switch, a transmitter-base having therein a fixed plate provided with a series of non-removable plugs, said plugs extending through the face of the base and projecting below the fixed plate, each plug having on opposite sides a spring-finger and

pass depending from the fixed plate to contact with said spring-finger, as set forth.

5. In an intercommunicating telephone-switch, a transmitter-base having therein a rigid insulating-plate, a series of round holes through the same, provided with oppositely disposed pins or grooves, in combination with plugs, having rounded bodies provided with spring-fingers on opposite sides and adapted to rest within the circular grooves, as set forth.

6. In an intercommunicating telephone-switch, the combination of a base and standard for a transmitter and a hinged receiver-hook, a disk within said base mechanically connected with the receiver-hook, a fixed insulating-plate above said disk having therein all the electrical terminals, and plugs through said plate projecting out of said base and extending below the insulating-plate into operative contact with said disk, metallic posts on opposite sides of each plug in electrical connection with the telephone-circuit, and spring-fingers on each plug adapted to contact with said posts when the plugs are depressed, as set forth.

701,988. WOOD-DESTROYING MECHANISM. VICTOR BERNARD, Tara, Canada. Filed June 10, 1901. Serial No. 95,457. (No model.)

Claim.—1. In an apparatus for destroying weeds on railway-tracks, the combination with a wheeled car, of a frame extending in its operative position outwardly from one side of said car, means whereby said frame is maintained in foldable and operative relation to said car, and a gang of wheel-cutters mounted on said frame, each wheel-cutter having a blade which is disposed approximately in a position parallel to the plane of the frame, as and for the purpose described.

2. In an apparatus for destroying weeds on railway-tracks, the combination with a wheeled car, of a frame-bar extending outwardly from one side of said car, means connecting said frame-bar foldably with the car and supporting the same in its extended operative position, and a gang of wheel-cutters on the frame-bar, each cutter having a cheek and a blade which is disposed on the cheek in a position approximately parallel to the frame upon which the cutter-cheek is clamped, as and for the purpose described.

3. An apparatus of the class described comprising a suitable frame, a pivoted bar having a handle and adapted to turn on a vertical axis, means carried by the frame to operate relation to the pivoted bar for limiting the latter to movement in a horizontal plane, and a gang of wheel-cutters, one of which is mounted on the pivoted bar and is shiftable therewith, substantially as described.

4. An apparatus of the class described comprising a suitable frame, a bar pivoted to said frame and having a handle, a keeper for limiting the bar to movement in a horizontal plane, and a gang of wheel-cutters, one of which is mounted on said bar and is shiftable therewith, substantially as described.

5. In an apparatus of the class described, the combination with a wheeled frame, of a hanger pivoted to said frame, means whereby the hanger may be adjusted with relation to the wheeled frame, a stay-rod attached to said hanger and to the frame, a frame-bar having a hinged connection with said hanger and extending outwardly therefrom, and a gang of wheel-cutters mounted on said frame-bar, substantially as set forth.

6. An apparatus of the class described comprising a suitable frame, a bar pivoted to said frame and having a handle, a keeper for limiting the bar to movement in a horizontal plane, and a gang of wheel-cutters each having an upwardly-extending cheek, one of said bars having its cheek attached to said bar, substantially as described.

7. In an apparatus of the class described, the combination with a wheeled frame, of a wood-destroying mechanism comprising a frame-bar, an arm pivoted to said frame-bar and extending rearwardly therefrom, a guide-bar attached to the frame-bar and embracing said pivoted arm, means for shifting the arm on its pivot, and a gang of bars one of which is attached to the pivoted arm and the other bars connected to the frame-bar, substantially as set forth.

8. In an apparatus of the class described, the combination with a wheeled frame, of a wood-destroying mechanism connected therewith and comprising a frame-bar extending outwardly from said wheeled frame, an extensible stay-rod attached to said outwardly-extending frame-bar and

to the wheeled frame, and a gang of wheel-cutters mounted on the frame-bar, substantially as set forth.

9. In an apparatus of the class described, the combination with a wheeled frame, of a hanger supported thereon, means for adjusting said hanger vertically, a frame-bar having a hinged connection with the hanger and extending outwardly from the wheeled frame, an extensible stay-rod connected with the frame-bar and with the wheeled frame, another stay-rod attached to the hanger and to the wheeled frame, and a gang of wheel-cutters mounted on the frame-bar, substantially as set forth.

10. In an apparatus of the class described, the combination with a wheeled frame, of a wood-destroying mechanism connected therewith and comprising an extensible frame-bar, means for clamping the members of said frame-bar adjustably together, means for foldably connecting the frame-bar to the wheeled frame and to support said frame-bar thereon when it is extended outwardly therefrom to assume an operative position, and a gang of wheel-cutters secured to the frame-bar, substantially as set forth.

11. In an apparatus of the class described, the combination with a wheeled frame, of a wood-destroying mechanism connected therewith and comprising a two-part frame-bar, clamping-brackets having the clotted plates arranged to receive the members of said frame-bar, means for clamping the frame-bar and the brackets adjustably together, and a gang of wheel-cutters each having a cheek which is fastened in one of the clamping-brackets, substantially as set forth.

701,984. BOTTLE-WASHER. RICHARD W. BAKER, Baitimore, Md. Filed Aug. 2, 1901. Serial No. 95,351. (No model.)

Claim.—The combination of a handle, having a cylindrical body, and running around on said cylindrical body a right-hand thread, and running around on said cylindrical body a left-hand thread, broader than said right-hand thread and crossing the same; an inner nut having a right-hand thread, corresponding with the right-hand thread of the bolt and in its upper face a recess, churning in the same direction with its thread, having a shoulder; a spring-washer provided with a central perforation, and with two tongues in one side, one turning slightly downwardly, and the other slightly upwardly; an upper nut having a left-hand thread corresponding with the left-hand thread of the bolt, and in its lower face one or more recesses, churning in an opposite direction from its thread, and having one or more shoulders; said nuts and washers adapted to be locked and unlocked at any point on the threaded part of the bolt, substantially as shown and described and for the purpose set forth.

701,985. BOTTLE-WASHER. RICHARD W. BAKER, Baitimore, Md., assignor of one-half to William F. Baker, Baitimore, Md. Filed Oct. 22, 1901. Serial No. 95,352. (No model.)

Claim.—1. A bottle-washer comprising a supporting rod or spindle and a flexible tube fitted longitudinally and having its ends inverted to form projecting loops.

2. A bottle-washer comprising a rod or spindle, and a flexible tube fitted longitudinally and having its ends inverted to form projecting loops, the outer surfaces of which are formed with projections.

3. A brush for washing bottles comprising a tubular body portion of yielding material, and radially-disposed loops projecting from the ends of the tubular body portion.

701,986. HEATING AND VENTILATING FURNACE. RICHARD W. BAKER, Baitimore, Md. Filed Oct. 22, 1901. Serial No. 95,353. (No model.)

Claim.—1. In a heating-furnace, the combination of a vertical flue, an inlet connection therein, heating-chambers connecting with the top and bottom of said flue, a damper in said vertical flue, independent air-flues in said lower chamber, an air-reheating chamber communicating with the atmosphere in said upper chamber and an inlet-pipe for said chamber passing through said lower chamber, for the purpose described.

2. In a heating-furnace, the combination of a vertical flue, an inlet connection therein, heating-chambers connecting with the top and bottom of said flue, a damper in said vertical flue, independent air-flues in said lower chamber, a hot-air chamber in said upper chamber, air inlet and outlet flues for said chamber, said inlet-flue extending down through the bottom of the upper chamber and partially through the lower chamber and a detachable extension projecting through the bottom of the lower chamber, shrouded on said flue, for the purpose described.

3. In a heating-furnace, the combination of a vertical flue, an inlet connection therein, heating-chambers connecting with the top and bottom of said flue, a damper in said vertical flue, independent air-flues in said lower chamber, a hot-air chamber in said upper chamber, air inlet and outlet flues for said chamber, said inlet-flue extending down through the bottom of the upper chamber and partially through the lower chamber, a damper in said flue intermediate said upper and lower chambers, and a downward extension projecting through the bottom of the lower chamber and carrying a ventilating-regulator.

4. In a heating-furnace, the combination of a vertical flue, an inlet connection therein, heating-chambers connecting with the top and bottom of said flue, a damper in said vertical flue, independent air-flues in said lower chamber, a hot-air chamber in said upper chamber, air inlet and outlet flues for said chamber, said inlet-flue extending down through the bottom of the upper chamber and partially through the lower chamber and a detachable extension projecting through the bottom of the lower chamber shrouded on said flue, a flaring collar on said extension forming a stop and provided with openings adapted to register with openings in the bottom of the lower chamber to form a register and an outwardly-flaring portion below said collar adapted to form a handhold for extending said register.

5. In a heating and ventilating furnace, the combination of an upper direct smoke-chamber D and a lower indirect smoke-chamber E, the main inlet-flue A having direct and indirect branches B and C respectively leading into said chambers, the regulating-damper G is in the direct branch, the air-heating chamber is in the upper smoke-chamber provided with air inlet and outlet flues, and the air-inlet flue passing through the lower chamber formed with lateral extensions at their ends for the purpose described.

6. In a heating and ventilating furnace, the combination of an upper direct smoke-chamber and a lower indirect smoke-chamber, the main inlet-flue having direct and indirect branches respectively leading into said chambers, the regulating-damper is in the direct branch, the air-heating flue passing through the lower chamber, the air-heating chamber is in the upper chamber provided with outlet and inlet flues, the air-inlet flue passing through the lower chamber and connected at its upper end with the air-heating chamber and the detachable extension shrouded on the lower end of said flue.

7. In a heating and ventilating furnace, the combination of an upper direct smoke-chamber and a lower indirect smoke-chamber, the main inlet-flue having direct and indirect branches respectively leading into said chambers, the regulating-damper is in the direct branch, the air-heating flue passing through the lower chamber, the air-heating chamber is in the upper chamber provided with air inlet and outlet flues, said inlet-flue passing through the lower chamber and connecting the air-heating chamber with the atmosphere and a rotatably-adjustable collar carried by the lower end of said flue and formed with openings adapted to register with openings in the bottom of the lower chamber to form a ventilating-regulator.

701,987. STARTING OR STOPPING MECHANISM. GEORGE H. BROWN, Benton, Ore. Filed Sept. 28, 1901. Serial No. 73,778. (No model.)

Claim.—1. The combination with opposite bearings, of a shaft mounted thereon, a driving member carried by the shaft, an endwise-shiftable drum mounted on the shaft in frictional operative relation to the driving member, a cylinder mounted upon one end of the shaft and exteriorly of the adjacent bearing, a piston working in the cylinder and having an operative connection with the drum to shift the same into engagement with the driving member, an inlet-pipe placing the center of the outer head of the cylinder and forming a bearing therefor, and a supporting-bracket carried by one of the bearings and connected to the supply-pipe to form a support therefor.

2. The combination with opposite bearings, of a rotatable shaft mounted thereon, a driving member carried by the shaft, an endwise-shiftable drum loosely mounted upon the shaft in operative relation to the driving member, a cylinder carried by and rotatable with one end of the shaft and loosely mounted on the adjacent bearing, a piston working in the cylinder and in operative relation to the drum to shift the same into engagement with the driving member, a supply-pipe centrally placing the outer head of the cylinder and forming a bearing therefor, an exhaust-valve carried by the supply-pipe, a service-pipe communicating with the supply-pipe between the exhaust-valve and the cylinder, a controlling-valve upon the service-pipe, a controlling-lever having a link connection between the two valves for simultaneously closing one and opening the other, and a bracket carried by the adjacent bearing and connected to the service-pipe to support the bearing for the outer end of the cylinder.

701,988. RECOIL-OPERATED FIREARM. JOHN H. BROWNE, Ogden, Utah. Filed Mar. 15, 1901. Serial No. 51,595. (No model.)

Claim.—1. In a recoil-operated firearm, the combination with the receiver thereof, of a recoiling barrel, a barrel-jacket secured to the receiver, a barrel-spring controlling the barrel, a buffer-spring controlling the barrel at a point to the rear of the rear end of the said barrel-spring, and a stop engaging with the barrel and bringing the barrel-spring into play after the barrel-spring has been compressed.

2. In a recoil-operated firearm, the combination with the receiver thereof, of a recoiling barrel, a barrel-jacket secured to the receiver, a barrel-spring controlling the barrel, a buffer-spring controlling the barrel at a point to the rear of the rear end of the said barrel-spring, and a stop located outside of the barrel-spring, engaging with the barrel and bringing the barrel-spring into play after the barrel-spring has been compressed.

3. In a recoil-operated firearm, the combination with the receiver thereof, of a recoiling barrel, a barrel-jacket secured to the receiver, a barrel-spring controlling the barrel, a buffer-spring controlling the barrel at a point to the rear of the rear end of the said barrel-spring, and a tubular stop

controlling a portion of the barrel-spring and engaging with the barrel to bring the buffer-spring into play after the barrel-spring has been compressed.

4. In a recoil-operated firearm, the combination with a receiver, of a recoiling barrel, a barrel-jacket secured to the receiver, a barrel-spring controlling the barrel, a buffer-spring also controlling the barrel, and a tubular stop engaging at one end with the buffer-spring and adapted to have its other end engaged by a projection from the barrel after the same has begun its recoiling movement.

5. In a take-down recoil-operated firearm, the combination with a receiver having its forward end formed with a bolt-hole, of a recoiling barrel, a barrel-jacket, a take-down head located at the rear end of the said jacket, adapted to fit the forward end of the receiver, and provided with a bolt-hole registering with the said bolt-hole therein, and a screw-bolt passing through the bolt-hole in the take-down head into the bolt-hole in the receiver, whereby the said head is fastened directly to the receiver.

6. In a take-down, recoil-operated firearm, the combination with a receiver formed at its forward end with a shallow recess, of a recoiling barrel, a barrel-jacket provided at its rear end with a take-down head consisting of a body receiving the rear end of the jacket, and formed with a bolt-hole, and of a plate or flange formed with a shoulder adapted to enter the said recess, a screw-bolt passing through the said bolt-hole in the said head and into the receiver and securing the head directly thereto.

7. In a recoil-operated firearm, the combination with a recoiling barrel, of a breech-closure, a hammer, and a dog engaging with the breech-closure to lock the same in its open position, and engaging with the hammer to prevent the same from falling until after the gun has been closed and locked.

8. In a recoil-operated firearm, the combination with the recoiling barrel and barrel extension thereof, of a breech-closure, a hammer, a dog engaging with the breech-closure to lock the same in its open position, and engaging with the hammer to prevent the same from falling until after the gun is closed and locked, and a lever engaging with the said dog and operated upon at its forward end by the barrel extension and by the breech-closure in the order named.

9. In a recoil-operated firearm, the combination with the recoiling barrel and barrel extension thereof, of a breech-closure, a hammer, a dog engaging at its rear end with the breech-closure to lock it in its open position, and formed at its forward end with two arms, one of which is provided with a hook for engaging with the hammer, and a lever engaging at its rear end with the other arm of the dog, and acted upon at its forward end by the barrel extension and the breech-closure in the order named, just before they reach their closed position.

701,989. SHUT FOR FIREARM. JOHN H. BROWNE, Ogden, Utah. Filed Dec. 15, 1901. Serial No. 52,665. (No model.)

Claim.—1. In a firearm, the combination with the barrel thereof, of a barrel-jacket formed with one or more clearance-openings, a right-piece located upon the jacket, and a ring located within the jacket in frictional contact with the inner periphery thereof, and adapted to have the right-piece connected with it through the said opening or openings which permit the right-piece to be adjusted sidewise upon the jacket, at which time the ring remains within the same.

2. In a firearm, the combination with the barrel thereof, of a barrel-jacket formed with one or more clearance-openings, a right-piece mounted upon the jacket, an expansible dog located within the jacket, and covers for connecting the right-piece and ring through the said clearance opening or openings and permitting the right to be adjusted upon the jacket for adjusting its position thereupon.

701,990. MAGNETIC CLUTCH. MARSHALL W. BOW, Schenectady, N. Y., assignor to the General Electric Company, a Corporation of New York. Original application filed Mar. 27, 1900. Serial No. 700,702. Divided and this application filed May 24, 1902. Serial No. 13,045. (No model.)

Claim.—1. In an electromagnetic clutch, the combination with an energizing-coil, of a normally excited demagnetizing-coil, such as to cause the clutch to release when the energizing-coil is deenergized.

2. In a clutch, the combination with a magnetizing-coil adapted to cause the clutch to operate when the coil is supplied with current, of a source of magnetomotive force substantially equal to the coercive force of the clutch, arranged to positively demagnetize the clutch when the main coil is deenergized.

3. In an electromagnetic clutch, the combination with metal forming a magnetic circuit, of a source of magnetomotive force acting on said circuit to operate the clutch, and an opposing and normally constantly acting source of magnetomotive force sufficient to neutralize the remanent magnetism and to cause the clutch to release when the first source of magnetomotive force ceases to act.

701,991. CURTAIN. EDWARD L. CARPENT and WILLIAM H. CARPENT, Detroit, Mich. Filed Mar. 17, 1902. Serial No. 93,394. (No model.)

Claim.—1. In a curtain, the combination with the curtain having an opening, of a longitudinally-movable cover to close said opening and a bowl pivoted to turn beneath the opening and extended upward therefrom and hinged to the cover whereby the cover is guided by the engagement of the bowl with the side of the opening in the floor.

2. In a curtain, the combination with a casing forming the body of the curtain and open at its top and bottom, of a longitudinally-mov-

able cover to close the upper end of said casing, and a pivoted bowl to close the lower end of said casing having a portion extended upward and hinged to the cover and adapted to guide the same.

3. In a curtain, the combination with a casing open at its top and bottom, of a longitudinally-movable cover to close the upper end of said casing, a bowl to close the lower end of the casing, having a portion extended upward and hinged to the cover, and a pivot upon which said bowl is free to turn and to slide.

4. In a curtain, the combination with a rectangular casing forming the body of the curtain and open at its top and bottom, of a cover to close the top of said casing, a bowl within said casing, having a portion extended upward and hinged to said cover, a rod extending transversely across the casing and a guide-loop on said bowl engaging said rod and holding the bowl in engagement therewith.

5. In a curtain, the combination with a rectangular casing forming the body of the curtain and open at its top and bottom, of a longitudinally-movable cover to close the upper end of said casing, a bowl having a curved bottom portion extended upward to the top of the casing and side flanges engaging the side wall of the casing, hinges connecting the upper end of said bottom portion with said cover, a rod extending through the walls of the casing and transversely across the same, guide-loops on the bottom portion of the bowl engaging said rod, and a rib on the casing forming a stop to engage the lower end of said bottom portion.

701,992. WHEEL. FREDERICK H. CANSA, New York, N. Y. Filed Oct. 23, 1901. Serial No. 95,495. (No model.)

Claim.—1. As an article of manufacture, a car-wheel comprising a body portion formed of a relatively hard material and a separate hub formed of a softer material suitable for a bearing member, said body portion and hub being secured together by a layer of binding material fusible at a lower temperature than either the body portion or the hub, and said hub having an interior bearing-surface adapted to permit rotation about a suitable journal.

2. As an article of manufacture, a car-wheel, comprising a cast-steel body portion and a separate hub formed of a softer material and secured to said body portion by a layer of metal fusible at a lower temperature than the metal of said body portion and hub, said hub having an interior bearing-surface adapted to permit rotation about a suitable journal, and having within it a chamber for lubricant communicating by a passage with said bearing-surface.

3. As an article of manufacture, a car-wheel, comprising a cast-steel body portion and a separate hub formed of a softer material, and a layer of cast metal filling the space between said body portion and said hub and securing the same together, said body portion and hub having on their adjacent surfaces projections whereby they are interlocked with the layer of cast metal binding them together.

701,993. VARIABLE-SPEED MECHANISM. JOHN E. CASE, Kansas City, Mo. Filed June 14, 1901. Serial No. 94,554. (No model.)

Claim.—1. In apparatus of the class described, the combination with a shaft, of a pulley mounted upon the shaft and comprising spaced flange-plates and an expansible rim located between the flange-plates, means for expanding and contracting the rim, said means including a head slidably mounted upon the shaft between the flange-plates and within the rim and having a connection with said rim, and mechanism for moving the head upon the shaft.

2. In apparatus of the class described, the combination with a shaft, of a pulley mounted upon the shaft and comprising spaced flange-plates and an expansible rim arranged between the flange-plates, means for expanding

and contracting the rim, said means including heads mounted upon the shaft between the face-plates and within the rim, said heads being movable toward and from each other, and operating mechanism for moving the heads.

3. In apparatus of the class described, the combination with a shaft, of a pulley mounted upon the shaft and comprising spaced face-plates and an expandible rim arranged between the face-plates, heads mounted upon the shaft between the face-plates and within the rim, said heads being movable toward and from each other, links connecting the rim and heads whereby the said rim will be expanded and contracted upon the movement of the heads, and operating mechanism for moving said heads.

4. In apparatus of the class described, the combination with a shaft, of a pulley mounted upon the shaft and comprising spaced face-plates and an expandible rim arranged between the face-plates, heads mounted upon the shaft between the face-plates and within the rim, said heads being movable toward and from each other, curved independent links connecting the rim and heads, whereby the said rim will be expanded and contracted upon the movement of the heads, and operating mechanism for moving said heads.

5. In apparatus of the class described, the combination with a shaft, of a pulley mounted upon the shaft and comprising spaced face-plates and an expandible rim located between the plates, means for expanding and contracting the rim, said means including a head slidably mounted upon the shaft between the plates and within the rim and having a connection with said rim, a collar slidably mounted upon the shaft exteriorly of the pulley and having a connection with the head, and means for sliding said collar.

6. In apparatus of the class described, the combination with a shaft, of a pulley mounted upon the shaft and comprising spaced face-plates and an expandible rim arranged between the plates, heads slidably mounted upon the shaft between the face-plates and movable toward and from each other, connections between the heads and rim, and adjusting elements located upon the shaft exteriorly of the pulley and movable toward and from each other, each of said adjusting elements being connected to one of the heads.

7. In apparatus of the class described, the combination with a shaft, of a pulley mounted upon the shaft and comprising spaced face-plates and an expandible rim arranged between the plates, heads slidably mounted upon the shaft between the plates and movable toward and from each other, connections between the heads and rim, adjusting elements located upon the shaft exteriorly of the pulley and movable toward and from each other, each of said adjusting elements being connected to one of the heads, and a screw-threaded shaft located between the adjusting elements and engaging therewith to move them toward and from each other.

8. In apparatus of the class described, the combination with a shaft, of a pulley mounted upon the shaft and comprising spaced face-plates and an expandible rim arranged between the plates, a head movably mounted upon the shaft between the face-plates, connections between the head and rim, a slidable adjusting element located exteriorly of the pulley, and means connecting the head and adjusting element, whereby when said element is moved, the head will also be moved.

9. In apparatus of the class described, the combination with a shaft, of a pulley mounted upon the shaft and comprising spaced face-plates and an expandible rim arranged between the face-plates, heads mounted upon the shaft between the face-plates and within the rim, said heads being movable toward and from each other, means connecting the rim and heads, collars slidably mounted on the shaft exteriorly of the pulley and con-

nected to the heads, and means engaging the collars to move them toward and from each other.

10. In apparatus of the class described, the combination with a shaft, of a pulley mounted on the shaft and comprising spaced face-plates and an expandible rim arranged between the face-plates, heads mounted upon the shaft between the face-plates and within the rim, said heads being movable toward and from each other, means connecting the rim and heads, collars mounted on the shaft exteriorly of the pulley and connected to the heads, slidably-mounted adjusting-blocks located contiguous to the shaft, each of said blocks having an engagement with one of the collars, and means for moving said blocks toward and from each other.

11. In apparatus of the class described, the combination with a shaft, of a pulley mounted on the shaft and comprising spaced face-plates and an expandible rim arranged between the face-plates, heads mounted upon the shaft between the face-plates and within the rim, said heads being movable toward and from each other, means connecting the rim and heads, collars mounted on the shaft exteriorly of the pulley and connected to the heads, slidably-mounted adjusting-blocks located contiguous to the shaft, each of said blocks having an engagement with one of the collars, a cover-shaft located between the adjusting-blocks and engaging therewith, and means for rotating the cover-shaft.

12. In apparatus of the class described, a driving and a driven element, each element comprising a shaft, a pulley mounted upon each shaft and having an expandible rim, means for expanding and contracting said rim, said means including heads mounted to move toward and from each other, adjusting elements spaced from each other and connected to the heads, and a cover-shaft located between the adjusting elements and provided with a worm-gear, in combination with a shaft having worms that engage the worm-gears of each element to rotate them in opposite directions.

701,294. ART OF FUELING IRON. ROBERT A. GARNER, FRIDBURG, Pa. Filed Mar. 12, 1901. Serial No. 61,896. (No specimens.)

Claim.—1. As an improvement in the art of fueling iron, the method herein described, which consists in forming an ore lining for the bottom of the hearth, charging the metal to be treated on the hearth, melting, boiling and stirring the metal adding ore to the charge during the boiling and stirring and finally boiling the charge, substantially as set forth.

2. As an improvement in the art of fueling iron, the method herein described, which consists in forming an ore lining for the bottom of the hearth, spreading ore on each lining, charging the metal to be treated onto the ore, melting, boiling and stirring the metal adding ore gradually to the molten metal and finally boiling the charge, substantially as set forth.

3. As an improvement in the art of fueling iron the method herein described, which consists in forming an ore lining for the bottom of the hearth, charging the metal to be treated, melting, boiling and stirring the metal adding ore in small quantities and from time to time after the metal has commenced to boil and finally boiling the charge, substantially as set forth.

701,295. IMPROVEMENT ELECTRIC LAMP. ADOLPH A. CHAILLON, Shelby, Ohio, assignor to the Shelby Electric Company, Shelby, Ohio, a Corporation of Ohio. Filed Oct. 28, 1900. Serial No. 23,856. (No model.)

Claim.—1. In an incandescent electric lamp, a filament having consecutive convolutions which form a helix whose axis is transverse to the axis of the lamp, the helix being flattened in a direction parallel with the axis of the lamp, substantially as described.

2. In an incandescent electric lamp, a filament coiled to form a helix, whose longitudinal axis is in a plane at right angles to the axis of the lamp, the helix being flattened in a direction parallel with the axis of the lamp, combined with a pear-shaped globe flattened on its end to correspond to the flattening of the helix, substantially as described.

3. In an incandescent electric lamp, a filament coiled in a plurality of convolutions to make a helix transverse to the axis of the lamp, the helix being flattened parallel with the axis of the lamp and terminating on opposite sides of its greater diameter, the filament-legs leading diagonally directly from each termination, substantially as described.

4. In an incandescent electric lamp, a filament coiled in a plane

ity of convolutions to make a helix having its longitudinal axis in a plane at right angles to the axis of the lamp, the convolutions being shortened parallel with the axis of the lamp, and the helix terminating on opposite sides of its greater diameter, the filament leading therefrom in two substantially straight diagonal legs, combined with a globe of a pear shape flattened on its dome and end carrying internally a mount in which the extreme ends of said filament-legs are fastened, substantially as described.

701,296. SMOKE-CONSUMER. DAVID CLINE and WILLIAM HOPKINS, St. Louis, Mo. Filed Feb. 12, 1902. Serial No. 64,287. (No model.)

Claim.—1. A smoke-consuming furnace comprising the ash-pit 5; the side walls 6 and 7 extending upwardly from the ash-pit; the bridge-wall 8 extending upwardly behind the ash-pit and having a forwardly-projecting portion 9 at its upper end; a grate mounted above the ash-pit; the perforated injector-pipes 11 and 12 mounted in the side walls a suitable distance above the grate; the perforated injector-pipe 13 mounted in the forwardly-extending projection 9 of the bridge-wall; and the steam air-injectors 15, 16 and 17 connected to the injector-pipes 11, 12 and 13, said injector-pipes being independently rotatable in their bearings, substantially as specified.

2. A smoke-consuming furnace comprising the ash-pit 5; the side walls 6 and 7 extending upwardly from the ash-pit; the bridge-wall 8 extending upwardly behind the ash-pit and having the forwardly-projecting portion 9 at its upper end; a grate mounted above the ash-pit; the perforated injector-pipes 11 and 12 mounted in the side walls a suitable distance above the grate; the perforated injector-pipe 13 mounted in the forwardly-extending projection 9 of the bridge-wall; and the steam air-injectors 15, 16 and 17 connected to the injector-pipes 11, 12 and 13; said injector-pipes being independently rotatable in their bearings; each of said steam air-injectors comprising a nipple 20 connected to the steam-pipes and having a reduced discharge-opening 22, the nipple 22 formed integrally with the nipple 20 and in alignment therewith, and the nipple 24 formed integrally with the nipples 20 and 22, said nipple 24 extending backwardly and outwardly at an angle of about forty-five degrees.

701,297. STATIONARY FENCE. ADOLPH H. COLE and GEORGE R. COLE, Altona, and WILLIAM H. COLE, Hagerstown, Canada. Filed Mar. 14, 1901. Serial No. 61,562. (No model.)

Claim.—1. In a stationary fence, the combination with the end or corner post suitably anchored and the strands connected thereto, of a triangular supporting-brace having its side members inclining downwardly and suitably supported, longitudinal bars connecting said brace with the upper part of the end post, and an inclined brace-rod connecting the upper end of said brace with the lower part of said post, substantially as described.

2. In a stationary fence, the combination with the end post and the strands connected thereto, of a triangular supporting-brace having its side members inclining downwardly and suitably supported, longitudinal bars connecting said brace with the upper part of the end post, and an inclined brace-rod connecting the upper end of said brace with the lower part of said post, and an inclined anchor-rod adjustably connected to the lower end of said post, substantially as described.

3. In a stationary fence, the combination with the end or corner post suitably anchored and the strands connected thereto, of a triangular supporting-brace having its side members inclining downwardly and suitably supported, longitudinal bars connecting said brace with the upper part of the end post, an inclined brace-rod connecting the upper end of said brace with the lower part of said post and means for adjusting said brace, substantially as described.

4. In a stationary fence, the combination with the end or corner post with means for anchoring the same at the base and the supporting-brace consisting of two diverging members suitably connected together at the top and bottom and supported at the base, of the longitudinal bar con-

necting the top portions of the post and brace and a flexible brace adjustable at the end thereof and connected to the top of the supporting-brace and to the bottom of the post as and for the purpose specified.

5. In a stationary fence, the combination with the end or corner post suitably supported at the base and the supporting-brace consisting of two diverging members suitably connected together at the top and bottom and supported at the base, of the longitudinal bar connecting the top portions of the post and brace, a flexible brace adjustable at one end and connected to the top of the brace and to the bottom of the post and a flexible brace connected to the bottom of the post at one end and to a suitable anchor in the ground for the opposite end of each brace as and for the purpose specified.

6. In a stationary fence, the combination with the double post and supporting-brace suitably held in position at the bottom, of the longitudinal bar adjustably connected to the top of the post and supporting-brace, the block holding the top of the supporting-brace together, the flexible brace extending through the top block and provided with a suitable nut at one end, the device suitably connected at the bottom of the brace at the opposite end and an anchoring means for securing the bottom of the post in position as and for the purpose specified.

7. In a stationary fence, the combination with the double post and supporting-brace suitably held in position at the bottom, of the longitudinal bar adjustably connected to the top of the post and supporting-brace, the block holding the top of the supporting-brace together, the flexible brace extending through the top block and provided with a suitable nut at one end, the device suitably connected at the bottom of the brace at the opposite end, a cross-block extending between the two members of the post, a wire extending therethrough and provided with a suitable nut and an anchoring means in the ground for the opposite end of each wire as and for the purpose specified.

701,298. PROCESS OF DEPOSITING METALS ON METALLIC SURFACES AND THE PRODUCT THEREOF. GUERARD CUYVER-OLAN, London, England, assignor, by name assignment, to the Electrolytic Syndicate, Limited, Westminster, London, England, a Corporation of Great Britain. Filed July 24, 1901. Serial No. 63,662. (No specimens.)

Claim.—1. The process of depositing also on metallic surfaces which process consists in applying to the metallic surface pulverulent also partially oxidized and in submitting the same to heat.

2. The process of depositing also on metallic surfaces which process consists in applying to the metallic surface pulverulent also partially oxidized and in submitting the same to heat in a closed chamber.

3. The process of depositing also on metallic surfaces which process consists in applying to the metallic surface pulverulent also partially oxidized and submitting the same to heat in the presence of carbon.

4. The process of depositing also on metallic surfaces which process consists in applying to the metallic surface what is known in commerce as zinc-dust and in submitting the same to heat.

5. The process of depositing also on iron surfaces which process con-

into applying to the iron surface zinc dust and in submitting the same to heat.

6. The process of depositing zinc on metallic surfaces which process consists in applying to the metallic surface pulverulent zinc containing not less than eight per cent. zinc oxide and in submitting the same to heat.

7. The process of depositing zinc on metallic surfaces which process consists in applying to the metallic surface pulverulent zinc containing not less than eight per cent. zinc oxide and in submitting the same to heat in a closed chamber.

8. The process of depositing zinc on metallic surfaces which process consists in applying to the metallic surface pulverulent zinc containing not less than eight per cent. zinc oxide and submitting the same to heat in the presence of a small percentage of carbon.

9. As a new product a metallic object with its surface covered with zinc having the following characteristics, a homogeneous coating of zinc, having a physical connection with the metal underneath, and having the appearance to the naked eye of a delicate silver gray and not shiny like galvanized articles and having the distinguishing appearance under the microscope of homogeneous particles free from crystalline structure.

701,299. ROTARY STEAM-ENGINE. JOHN F. GRAM and THOMAS V. FLEMING, Paris, Ill. Filed Feb. 14, 1901. Renewed Apr. 24, 1902. Serial No. 104,529. (No model.)

Claim.—1. In a rotary steam-engine, the combination with the cylinder, of an eccentric piston, said cylinder being provided with gate or abutment chambers diverging toward the cylinder-space, gates or abutments adapted to work in said chambers, and means for positively reciprocating in alternation the gates or abutments within their chambers by the movement of the engine, substantially as set forth.

2. In a rotary steam-engine, the combination with a cylinder having gate or abutment chambers diverging toward the cylinder-space and arranged at diametrically opposite points in its circumference, and radially disposed, of an eccentrically-mounted piston provided with concentric inlet and exhaust ports on its ends communicating with inlet and exhaust ports which extend through and lead out at the periphery of the piston at different points in the circumference of the piston, gates or abutments mounted to reciprocate in said chambers, and clamps connecting the gates or abutments to the piston and designed to reciprocate said gates or abutments in alternation, substantially as set forth.

701,800. VALVE-GEAR. HENRY I. GRAM and WALTER S. GRAM, Cincinnati, Ohio, assignors of one-third to Stewart Shultz, Cincinnati, Ohio. Filed Mar. 2, 1901. Serial No. 48,495. (No model.)

Claim.—The combination of a crank-shaft; an eccentric pivoted in the line of the crank, permanently eccentric to the extent of the lap of

the valve, to swing across the crank-shaft; a collar splined to the crank-shaft; a flattened surface on the crank-shaft; a bell-crank lever pivoted to the flattened surface on the crank-shaft; a slot in the eccentric; washers engaging the slot and having concave spherical bearings; a ball on one arm of the bell-crank lever engaging the spherical bearings in the washers; an engagement between the other arm of the bell-crank lever and the collar; and means for moving the collar longitudinally on the shaft, substantially as specified.

701,801. HARVESTER ATTACHMENT. CHARLES F. CRAYER, Harvey, Ill. Filed May 4, 1902. Serial No. 15,462. (No model.)

Claim.—1. A harvester attachment comprising a series of lifting-fingers each comprising a single curved bar and extending beyond the points of the guards, the lifting portions whereof extend from points above and in front of the points of the guards obliquely downwardly and forwardly while the opposite finished ends extend beneath and below the guards and are connected to the front of the finger-bar, substantially as described.

2. A harvester attachment comprising in combination a series of lifting-fingers and a common bar to which said fingers are attached, said bar being removably secured to the front of the finger-bar beneath the guards thereof and said fingers being rigidly attached thereto and curved upwardly to points above the points of the guards and thence obliquely downward, substantially as described.

3. A lifting-finger for lodged or fallen grain comprising a single curved bar having its inner portion connected to the front of the finger-bar below the upper surface of the guard and its body curved upwardly so as to clear the plane of the point of the guard and thence curved downwardly in front of the guard and its extremity being slightly upturned, substantially as described.

4. A harvester attachment comprising a series of lifting-fingers each formed of a single curved bar and extending beyond the points of the guards, the lifting portions whereof extend from points above and in front of the points of the guards obliquely downwardly and forwardly while the opposite attached ends are located below the top of the guards and in front of the finger-bar whereby the grain is lifted above the guards before it passes between the latter and the reel-blades may be carried into close proximity with the tops of the guards without encountering the lifting-fingers, substantially as described.

701,802. WHEEL. GEORGE E. CUNNEY, Akron, Mo. Filed Jan. 11, 1902. Serial No. 50,211. (No model.)

Claim.—1. In a vehicle-wheel, a rim, a hub provided with a plurality of radial spoke-retaining cases, a spring set in each of said cases, means for confining said springs in said cases, and a series of spokes, each spoke having one end secured to the rim and the other end to one of said springs midway its length, whereby the hub is yieldingly supported.

2. In a vehicle-wheel, a rim, a hub provided with a plurality of radial spoke-retaining cases, a series of spokes and a series of springs set in each of said spoke-retaining cases, one end of said springs being secured to the bottom of said cases, each of said spokes having one end secured to the rim and the other end to a spring midway its length.

3. In a vehicle-wheel, a rim, a hub provided with a plurality of radial spoke-retaining cases, a coil-spring set in each of said cases, a threaded cap adapted to screw into the outer end of said cases and bear against the end of the spring therein compressing said spring and a plurality of spokes each having one end secured to the rim of the wheel and the other end passing through the cap and being secured to said spring midway its length.

4. In a vehicle-wheel, a rim, a hub provided with a plurality of radial spoke-retaining cases, a spring set in each of said cases, a cross-head secured to the spring midway its length and adapted to have sliding contact with the walls of said cases and a plurality of spokes each having one end secured to the rim and the other end secured to said cross-head and a cap fitting the outer end of said spoke-retaining cases and adapted to hold said springs therein.

5. In a vehicle-wheel, a rim, a hub provided with a plurality of radial spoke-retaining cases, a double coil-spring, wound from the middle into a double coil set in each of said cases, means for confining said spring in said cases and a series of spokes, each spoke having one end secured to the rim and the other end to one of said springs intermediate its length, whereby the hub is yieldingly supported.

6. In a vehicle-wheel, a rim, a hub provided with a plurality of spoke-retaining cases, a spring set in each of said cases, means for confining said springs in said cases normally under some degree of tension and a series of spokes, each spoke having one end secured to the rim and the other end to one of said springs intermediate its length, whereby the hub is yieldingly supported.

701,803. GAS-BURNER. CHARLES W. CUNNEY, Columbus, Ohio. Filed Sept. 26, 1901. Serial No. 75,245. (No model.)

Claim.—In a gas-burner, the combination with a valve-casing; a gas-supply pipe leading downwardly therefrom, said casing having formed therein an internal chamber and an inverted valve-seat in the top of said chamber, and a port leading therefrom; a vertically-arranged valve loosely mounted in the casing and controlling the vertical port said valve having

a port in line with the port of the casing and adapted to be in communication therewith; said casing being provided with a part at right angles to the valve's port; and burner-supporting arms radiating from the casing and in communication with said chamber; of a pipe extending from the casing in communication with its right-angled port; and a tube at right angles to the said pipe having a valve-seat in its end, and a vertically-adjustable valve in the end of the pipe adapted to contact the seat in the tube and control the flow of gas through the tube.

701,804. CHURCH. CLARENCE A. DART, Wash. D. C. Filed Jan. 29, 1902. Serial No. 50,284. (No model.)

Claim.—The combination with a jar 1 having the marginal head 2, of the chamber 3, the supporting-arms 4 and jar-cover 5 secured to the base end of said standard, by the clamping-arms 10, which arms 4 have the depending clamping ends 6, the heater-shaft 12 mounted in said standard and provided at its depending end with radial heater-arms, the piston on the upper end of said shaft 12, and the crank-equipped gear working with said piston and mounted on a bearing carried by said shaft 2, substantially as described.

701,805. HOLDER FOR HANDLES OF KITCHEN UTENSILS. WILLIAM R. DAUFREY, Montgomery, Ala. Filed Oct. 3, 1901. Serial No. 77,757. (No model.)

Claim.—1. A device of the class described comprising two semi-tubular handle-sections, and a lining of flexible material secured to the inner faces of the tubular handle-sections and connecting the same to form a hinge-joint, said material being doubled and interposed between the sections at the said hinge-joint and presenting sufficient resiliency to open the sections automatically when the said sections are free to open, substantially as described.

2. As an improved article of manufacture a holder for kitchen utensils comprising two semi-tubular sections with an inner lining of fabric forming the hinge therefor and having one edge extended beyond the sections and deflected at an angle.

701,806. PHOTOGRAPHIC-PLATE HOLDER. WILLIAM E. L. DAVIES, Southwick, England. Filed Dec. 3, 1901. Serial No. 54,257. (No model.)

Claim.—1. In a photographic-plate holder adapted for three-color photography, a plate carrier hinged within the slide turning into position at right angles to the slide for exposure and a screen-reflector hinged behind the carrier adapted to turn through about half a right angle and to reflect part of the light from the lens upon the horizontal plate in the carrier, substantially as herein described.

2. In a photographic-plate holder, having a plate fixed in the back,

a hinged plate-carrier C at the front adapted to take up a horizontal position for exposure, a hinged screen-reflector D between the back and the carrier C and an attachment E retaining the reflector at an angle of about forty-five degrees to the slide when opened, the whole adapted for three-color photography, substantially as herein described and shown.

701,807. ELECTRICAL IGNITION APPARATUS. HENRY J. DAVIES and HENRY A. DAVIES, Canterbury, England. Filed Jan. 20, 1901. Serial No. 44,948. (No model.)

Claim.—1. In electrical ignition apparatus, the combination with a dynamo having an armature of interrupted-pole type, of a loose pinion, a first wheel fixed to the said loose pinion, a second wheel fixed to the armature, a double wheel gearing with the first and second wheels respectively and means for moving the axis of the said double wheel about the axis of the armature, substantially as and for the purpose set forth.

2. In electrical ignition apparatus, the combination with a dynamo, an induction-coil, a primary circuit, and a motor, of a disk, a number of recesses in the said disk, a fulcrum, a metallic lever movable on the said fulcrum, a blade-spring in electrical connection with the said lever, an insulated terminal, contact-points on the said insulated terminal and on one end of the said lever, a spring adapted to impel both the other end of the said lever into contact with the periphery of the disk and the said points into contact with each other, a sparking plug in each cylinder, metallic studs equalling in number the cylinders of the motor in electrical connection with the respective sparking plugs and arranged in a circular series concentric with the axis of the disk, a central metallic stud in electrical connection with one end of the secondary winding of the induction-coil, a finger carried by the disk and pivoted on the said central stud, and means for rotating the said finger with the said disk once for each cycle of the motor, such means being adapted to bring the outer end of the finger into contact with each of the studs in the circular series in turn, substantially as and for the purpose set forth.

701,808. ENVELOPES. WILLIAM A. DEAN, Chicago, Ill. Filed Mar. 16, 1908. Serial No. 53,366. (No model.)

Claim.—1. An envelop or wrapper, consisting of a face portion, a pair of side flaps thrown the outer meeting margins of which are united to constitute the back, a tail-flap underlying and unattached to said connected side flaps and having an extension in the nature of an anchoring-flap which folds over and is unattached to the outside of said connected side flaps at the upper and thereof, and a top flap adapted to be folded down over said anchoring-flap, substantially as described.

2. An envelop or wrapper, consisting of a face portion, a pair of in-

tegral side flaps thrown the outer meeting margins of which are united to constitute the back, an integral tail-flap underlying and unattached to said connected side flaps and having an extension in the nature of an anchoring-flap which folds over and is unattached to the outside of said connected side flaps at the upper and thereof, and an integral top flap adapted to be folded down over said anchoring-flap and to be sealed to the back of said connected side flaps below said anchoring-flap, substantially as described.

3. An envelop or wrapper, consisting of a face portion, a pair of integral side flaps thrown the outer meeting margins of which overlap and are united to constitute the back, an integral tail-flap folded back upon said face portion beneath said connected side flaps and unattached thereto and having an extension in the nature of an anchoring-flap which folds over and is unattached to the outside of said connected side flaps at the upper and thereof, and a top flap adapted to be folded down over said anchoring-flap and to be sealed to the back of the side flaps below said anchoring-flap, substantially as described.

4. An envelop or wrapper, consisting of a face portion, a pair of side flaps thrown the outer meeting margins of which are united to constitute the back, a tail-flap underlying and unattached to said connected side flaps and having an opening formed therethrough near its base, an anchoring-flap integral with and constituting an extension of said tail-flap folded over the outside of said connected side flaps at the upper and thereof and unattached thereto, and a top flap adapted to be folded down over said anchoring-flap, substantially as described.

701,809. PORTABLE JEWEL-CASE. DR. EDWARD J. DUTCH. New York, N. Y. Filed Dec. 21, 1901. Serial No. 48,548. (No model.)

Claim.—1. In a device of the character described, the combination with a casing, composed of two separate sections hinged together, of partitions dividing one of said sections longitudinally into compartments, a transversely-disposed partition dividing one of said compartments, a flexible covering inclosing said partition, a cover for one of said compartments supported by said covering, a plurality of cross-pieces arranged transversely of one of said compartments, at spaced distances, and a web covering for said cross-pieces between which are adapted to be inserted rings or the like.

2. In a device of the class described, the combination with a case comprising a pair of separate sections hinged together, of partitions arranged longitudinally and transversely within said sections, dividing the same into compartments, cross-pieces arranged transversely at spaced intervals in one of said compartments, a soft fabric covering said cross-pieces, a covering for said partitions, a cover secured by the covering of one of said partitions adapted to close one of said compartments, a flexible flange carried by one of said hinged sections, against which the edge of said cover impinges, and flexible strips arranged transversely of the opening section, secured to the same at intervals.

3. In an article of the class described, the combination of the separate sections 1, 2, hinged together at the bottom, the section 2 having a carrying-handle, a longitudinal strip 14, a flexible rim 12, and a cover hinged to the strip 14, its free end being adapted to bear against said flexible rim.

701,810. TREATMENT OF WASTE MATERIAL FOR USE IN THE MANUFACTURE OF PAPER. ROBERT DUNHAM, Monroeville, Germany. Filed Oct. 17, 1906. Serial No. 33,388. (No model.)

Claim.—1. A machine for treating paper-waste material comprising an exhauster, suction-pipes leading to the exhauster, a cyclone having a ventilating-top, a conduit connecting the exhauster with the cyclone, a water-spraying device within the ventilating-top adapted to play on the material falling from the conduit and a filter-estimating apparatus into which the cyclone discharges.

2. A machine for treating paper-waste material comprising an exhauster, suction-pipes leading to the exhauster, a cyclone having a ventilating-top, a conduit connecting the exhauster with the cyclone, a water-spraying device within the ventilating-top, a spraying-ring surrounding the

spraying device, and a filter-estimating apparatus into which the cyclone discharges.

3. A machine for treating paper-waste material comprising an exhauster, suction-pipes leading to the exhauster, a cyclone having a ventilating-top, a conduit connecting the exhauster with the cyclone, a water-spraying device within the ventilating-top, an upper spraying-ring, a lower spraying-ring, and a filter-estimating apparatus into which the cyclone discharges.

4. A machine for treating paper-waste material comprising an exhauster, suction-pipes leading to the exhauster, a cyclone having a ventilating-top, a conduit connecting the exhauster with the cyclone, a water-spraying device within the ventilating-top, an upper spraying-ring, a lower spraying-ring, a spraying-ring at the discharge end of the cyclone, and a filter-estimating apparatus into which the cyclone discharges.

5. A machine for treating paper-waste material comprising an exhauster, suction-pipes leading to the exhauster, a cyclone having a ventilating-top, a conduit connecting the exhauster with the cyclone, a water-spraying device within the ventilating-top, a spraying-ring at the discharge end of the cyclone, and a filter-estimating apparatus into which the cyclone discharges.

6. A machine for treating paper-waste material comprising an exhauster, suction-pipes provided with separate-bases and leading to the exhauster, a cyclone having a ventilating-top, a conduit connecting the exhauster with the cyclone, a water-spraying device within the ventilating-top, and a filter-estimating apparatus into which the cyclone discharges.

701,811. PRESS-PRESS. ALFRED H. DUNHAM, New York, Canada, assignor of one-half to William Irvine, Toronto, Canada. Filed June 22, 1901. Serial No. 48,549. (No model.)

Claim.—1. In a press, the combination with the die-block containing a plurality of dies, of a compressing-plunger and an ejecting-plunger suitably supported and deriving a reciprocating movement, means for moving each succeeding die from underneath the compressing-plunger to a point below the ejecting-plunger and a cleaning and ejection device rigidly connected to the plungers and deriving a simultaneous reciprocating movement with the plungers into an empty die as and for the purpose specified.

2. In a press, the combination with a rotatable die-block suitably journaled and a plurality of dies located therein at equal distances apart,atchet-shaped notches in the periphery of the die-block, a lever suitably journaled on a counter-shaft, a push-rod pivotedly connected to the lever and thereof, a spring for holding each push-rod in engagement, a cam on the main shaft designed to operate against the upper end of the lever and a surrounding strap connected to the upper end of the lever and engaging with the cam as and for the purpose specified.

3. The combination with the die-block and dies and the notched-shaped notches in the periphery of the die-block, of the lever and push-rod connected to the lever and thereof and means for imparting a springing movement to lever and the eccentric pivot-block for the lever held on

the end of a pin and extending through a circular hole in the lever and adjustable means for holding each eccentric block in position as and for the purpose specified.

4. In a device of the class described, the combination with the operating-lever for the die-block, of an eccentric pivot-block suitably supported and the L-shaped bolts having the end extending over the flange of the block and extending through the lever, and one on the opposite end of the bolt whereby the eccentric pivot-block is clamped into any position in which it may be set as and for the purpose specified.

5. In a device of the class described, the combination with the cylindrical die-block having an annular groove in the periphery thereof and the bed on which the same is supported and journaled, of the diametrically opposite plates fitting into the annular groove in the die-block and means for securing them to the bed as and for the purpose specified.

6. In a device of the class described, the combination with the bed and the die-block suitably supported on same, as to have a space between the block and the bed, of the die suitably held in the block and provided at the bottom with a flaring discharge portion as and for the purpose specified.

7. In a device of the class described, the combination with bed and the die-block suitably supported on same, as to have a space between the block and the bed, of the die suitably held in the block and provided at the bottom with a flaring discharge portion as and for the purpose specified.

8. In a device of the class described, the combination with the bed and the die-block and the die and plunger, of a block situated in the bed directly beneath the die and a resilient-spring extending underneath the block as and for the purpose specified.

9. In a device of the class described, the combination with the bed, and a rotatable die-block provided with a plurality of dies at equal distances apart, of the central arbor having a suitable head and extending through the center of the die-block and through the bed, the collar through which said arbor extends, each collar fitting into a recess in the bed and in the block and supporting each block above the bed and a nut at the lower end of the arbor for securing it in position as and for the purpose specified.

10. In a device of the class described, the combination with the die-block containing a plurality of dies, of the compressing-plunger and companion ejecting-plunger, said ejecting-plunger having its end extending below the level of the compressing-plunger, substantially as described.

11. In a device of the class described, the combination with the die-block containing a plurality of dies having flaring discharge ends, of the compressing-die and companion ejecting-die having the end extending below the level of the compressing-die and tapered as shown.

12. In a device of the class described, a die-chamber comprising a tube having a web of suitable material at the lower end, each tube being designed to contain oil and having perforations extending through the bottom and of the same to the web as and for the purpose specified.

13. In a device of the class described, the combination with a die-block suitably supported and means for holding each block from vertical displacement comprising an annular channel adapted to engage the edge of a stationary plate as and for the purpose specified.

14. The combination with the die-block, dies suitably held therein and means on said dies for preventing vertical displacement thereof, substantially as described.

15. In a device of the class described, the combination with the bed and the rotatable block suitably journaled and supported a slight distance above the bed, of the die provided with an outwardly-projecting lower end of such a depth as to allow of a limited movement upwardly of the die in order to permit of the expansion of the block after being compressed as and for the purpose specified.

16. The combination with the die-block and dies having an annular enlargement, of the bed having an opening therein designed to be always opposite the discharging-die, such annular enlargement of the die being designed to rest on the edge of the opening as and for the purpose specified.

701,812. CONVEYER FOR MIXING-MACHINES OR THE LIKE.
GUYTON T. DRAKE, Chicago, Ill. Filed June 7, 1901. Serial No. 63,998.
(No model.)

Claim.—1. In a mixing apparatus of the character described, the combination with a vehicle, of a power-shaft extending longitudinally beneath said vehicle, a depending bearing secured to said vehicle within which said shaft is journaled, a horizontal plate mounted upon said vehicle beneath the discharge end of the mixer, a vertical bearing depending from said plate, a turn-table supported by said horizontal plate, a king-bolt journaled in said vertical bearing and passing through said horizontal plate and turn-table, meshing gears secured to the power-shaft and lower end of the king-bolt, a stub-shaft journaled upon said turn-table, meshing beveled gears secured to said stub-shaft and the upper end of the king-bolt, a frame pivotally supported by said turn-table, and a conveyor carried by said frame and driven by said stub-shaft, substantially as described.

2. In combination with a mixer or the like, a turn-table thereon, a king-bolt constituting the pivot of said turn-table, a conveyor connected to the turn-table, means for transmitting motion to the king-bolt, means for transmitting motion from the king-bolt to the conveyor and a supporting-structure for the lower portion of the king-bolt, comprising the tubular portion of and the lateral arm or brace of, substantially as described.

3. In a mixing apparatus of the character described, the combination with a support, of a turn-table mounted thereon, a king-bolt pivotally securing said turn-table to said support, brackets secured to the upper surface of said turn-table, a conveyor-frame, a rotatable shaft extending through the lower end of said frame and through said brackets and constituting a pivotal connection between said frame and brackets, a roller beneath the discharge end of the mixer mounted on said shaft, a second roller journaled in the outer end of said conveyor-frame, a conveyor passing around said roller, connections between said king-bolt and a source of power for rotating the former, a stub-shaft rotatably mounted above said turn-table in one of said brackets, meshing gears secured to said king-

bolt and said stub-shaft, and means interposed between said stub-shaft and said second roller for driving the conveyor, substantially as described.

4. In a mixing apparatus of the character described, the combination with a support, of a turn-table mounted thereon, a king-bolt pivotally securing said turn-table to said support, brackets secured to the upper surface of said turn-table, a conveyor-frame, a rotatable shaft extending through the lower end of said frame and through said brackets and constituting a pivotal connection between said frame and brackets, a roller beneath the discharge end of the mixer mounted on said shaft, a roller adjustably mounted in the outer end of said frame, an endless conveyor passing around said roller, a power-shaft operatively connected to said king-bolt for rotating the latter, a stub-shaft rotatably mounted in one of said brackets, meshing gears secured to said king-bolt and stub-shaft, sprocket-wheels secured to said stub-shaft and the roller adjustably mounted in the conveyor-frame, and a sprocket-chain connecting said sprocket-wheel whereby the conveyor is driven, substantially as described.

701,818. FASTENING FOR ARTICLES OF CLOTHING. JOHN M. DUFFY, Philadelphia, Pa. Filed Jan. 7, 1902. Serial No. 64,748. (No model.)

Claim.—1. A fastener of the character stated, consisting of an attaching-plate, and a plurality of tongues extending therefrom in the same direction, having their outer ends free of each other and said plate, at the same side of the fastener.

2. In a fastener of the character stated, an attaching-plate and a plurality of tongues which later are connected at the same end with said plate, the latter having side pieces, the outer tongues being formed from said plate between said side pieces, and the outer tongue being formed from said outer tongues, said tongues being free from each other and said side pieces, and their outer ends being on the same side of the fastener.

701,814. ASSEMBLY VOTING-MACHINE. FRANK L. DYER, Montclair, N. J. Filed Apr. 9, 1901. Serial No. 64,971. (No model.)

Claim.—1. In an apparatus for ascertaining and registering the sense of an assembly, the combination with a receiver, of a series of transmitting-stations, a contact device in each transmitting-station, and a lock the movement of which effects the operation of the contact device, substantially as set forth.

2. In an assembly voting apparatus, the combination with a transmitter employing a contact device and a lock the barrel of which effects the operation of said contact device, of a receiver electrically connected to and operated by said transmitter, substantially as set forth.

3. In an assembly voting apparatus, the combination with a transmitter employing a contact device, a lock the barrel of which effects the operation of said device, and means for locking the contact device in the position to which it may be moved, of a receiver electrically connected to and operated by said transmitter, substantially as set forth.

4. In an assembly voting apparatus, the combination with a transmitter employing a contact-disk, two contacts cooperating therewith, and a lock the barrel of which effects the operation of said disk, of a receiver electrically connected to and operated by said transmitter, substantially as set forth.

5. In an assembly voting apparatus, the combination with a trans-

mitter employing a contact-disk, two contacts cooperating therewith, a lock the barrel of which effects the operation of said disk, and means for locking the disk in either extreme position, of a receiver electrically connected to and operated by said transmitter, substantially as set forth.

6. In an assembly voting apparatus, the combination with a transmitter employing a contact-disk, means for operating said disk, and means for locking said disk in either extreme position of movement, of a receiver electrically connected to and operated by said transmitter, substantially as set forth.

7. In an assembly voting apparatus, the combination with a transmitter employing a contact-disk, two contacts cooperating therewith, means for operating the disk, and means for locking the disk in either of its extreme positions, of a receiver electrically connected to and operated by said transmitter, substantially as set forth.

8. In an assembly voting apparatus, the combination with a transmitter employing a contact-disk, a pair of contacts cooperating therewith, means for locking the disk in either of its extreme positions, and a restoring-magnet for returning the disk, of a receiver electrically connected to and operated by said transmitter, substantially as set forth.

9. In an assembly voting apparatus, the combination with a transmitter employing a contact-disk, a pair of contacts cooperating therewith, a restoring-magnet, an armature for said magnet for locking the disk in either of its extreme positions, of a receiver electrically connected to and operated by said transmitter, substantially as set forth.

10. In an assembly voting apparatus, the combination with a transmitter employing a contact-disk, a pair of contacts cooperating therewith, a restoring-magnet, an armature for said magnet for locking the disk in either of its extreme positions, a dotted extension on said armature, and a pin on the disk cooperating with said dot, of a receiver electrically connected to and operated by said transmitter, substantially as set forth.

11. In an assembly voting apparatus, the combination with a transmitter employing a contact-disk, a pair of contacts cooperating therewith, a restoring-magnet, an armature for said magnet for locking the disk in either of its extreme positions, a dotted extension on said armature, and two pins on the disk cooperating with said dot, of a receiver electrically connected to and operated by said transmitter, substantially as set forth.

12. In an assembly voting apparatus, the combination with a transmitter employing a contact-disk, a pair of contacts cooperating therewith, means for locking the disk in either of its extreme positions, and a lock the barrel of which effects the movement of said disk, of a receiver electrically connected to and operated by said transmitter, substantially as set forth.

13. In an assembly voting apparatus, the combination with a transmitter employing a contact-disk, a pair of contacts cooperating therewith, means for locking the disk in either of its extreme positions, a restoring-magnet for unlocking the disk, and a lock the barrel of which effects the movement of said disk, of a receiver electrically connected to and operated by said transmitter, substantially as set forth.

14. In an assembly voting apparatus, the combination with a transmitter employing a contact-disk, a pair of contacts with which said disk cooperates, means for locking the disk in either of its extreme positions, and means for manually unlocking the disk, of a receiver electrically connected to and operated by said transmitter, substantially as set forth.

15. In an assembly voting apparatus, the combination with a transmitter employing a contact-disk, a pair of contacts with which said disk cooperates, means for locking the disk in either of its extreme positions, and means for manually and electrically unlocking the disk, of a receiver electrically connected to and operated by said transmitter, substantially as set forth.

16. In an assembly voting apparatus, the combination with a transmitter employing a contact-disk, a pair of contacts with which said disk cooperates, a restoring-magnet, an armature therefor for locking the disk in either of its extreme positions, and means for manually operating said armature for unlocking the disk, of a receiver electrically connected to and operated by said transmitter, substantially as set forth.

17. In an assembly voting apparatus, the combination with a transmitter employing a contact-disk, a pair of contacts cooperating therewith, means for locking the disk in either of its extreme positions, and two spring-actuated levers for entering the disk when unlocked, of a receiver electrically connected to and operated by said transmitter, substantially as set forth.

18. In an assembly voting apparatus, the combination with a transmitter employing a contact-disk, a pair of contacts cooperating therewith, means for locking the disk in either of its extreme positions, two spring-actuated levers for entering the disk when unlocked, and hooks on the ends of said levers for limiting the movement of said disk in either direction, of a receiver electrically connected to and operated by said transmitter, substantially as set forth.

19. In an assembly voting apparatus, the combination with a transmitter employing a disk, means for actuating the same, means for locking the disk in either of its extreme positions, and an indicator movable with

the disk to give a visual indication of its position, of a receiver electrically connected to and operated by said transmitter, substantially as set forth.

20. In an assembly voting apparatus, the combination with a transmitter employing a disk, means for actuating the same, means for locking the disk in either of its extreme positions, and a screw movable with the disk and indicating the position thereof, of a receiver electrically connected to and operated by said transmitter, substantially as set forth.

21. In a receiver for the purpose described, the combination of a carrying-body, two lines of type carried thereby, an impression-roller cooperating with each line, a paper strip passing over each impression-roller, a slide-head, means for operating said slide-head, and means controlled electrically for engaging the slide-head with either impression-roller, substantially as set forth.

22. In a receiver for the purpose described, the combination of a carrying-body, two lines of type carried thereby, an impression-roller cooperating with each line, a paper strip passing over each impression-roller, a slide-head, means for operating said slide-head, and a polarized relay for engaging the slide-head with either impression-roller, substantially as set forth.

23. In a receiver for the purpose described, the combination of a carrying-body, two lines of type carried thereby, a swinging frame mounted above each line, an impression-roller in each frame, a slide-head, means for operating the slide-head, a tongue carried by the slide-head for engaging either of said frames, and means for operating said tongue electrically, substantially as set forth.

24. In a receiver for the purpose described, the combination of a carrying-body, two lines of type carried thereby, a swinging frame mounted above each line, an impression-roller in each frame, a slide-head, means for operating the slide-head, a tongue carried by the slide-head for engaging either of said frames, and a polarized relay for operating said tongue, substantially as set forth.

25. In a receiver for the purpose described, the combination of a carrying-body, two lines of type carried thereby, a swinging frame mounted above each line, an impression-roller in each frame, a slide-head, a cam-shaft for operating the slide-head, a tongue carried by the slide-head for engaging either of said frames, a polarized relay for operating said tongue, and means carried by the cam-shaft for resetting said polarized relay, substantially as set forth.

26. In a receiver for the purpose described, the combination of a printing-drum, two lines of type carried thereon, a swinging frame cooperating with each line, an impression-roller in each frame, a slide-head, means controlled electrically for causing the slide-head to depress either of said swinging frames, and means for reciprocating said slide-head and for rotating said printing-drum, substantially as set forth.

27. In a receiver for the purpose described, the combination of a printing-drum carrying two lines of type, two impression-rollers cooperating with said lines, a slide-head, a tongue carried by said slide-head, means for electrically engaging said tongue with either impression-roller, and means for simultaneously reciprocating said slide-head and rotating said drum, substantially as set forth.

28. In a receiver for the purpose described, the combination of a printing-drum carrying two lines of type, an impression-roller cooperating with each line, a slide-head, a tongue carried by the slide-head, a polarized relay, connections between the relay and said tongue, and means for reciprocating the slide-head, substantially as set forth.

29. In a receiver for the purpose described, the combination of a printing-drum carrying two lines of type, an impression-roller cooperating with each line, a slide-head, a tongue carried by the slide-head, a polarized relay, connections between the relay and said tongue, and means for reciprocating the slide-head and for rotating the polarized relay, substantially as set forth.

30. In a receiver for the purpose described, the combination of a printing-drum carrying two lines of type, an impression-roller cooperating with each line, a slide-head, a main shaft, a cam on said shaft for reciprocating the slide-head, a tongue on the slide-head, means for electrically engaging said tongue with either impression-roller, and connections between said shaft and the printing-drum for rotating the latter, substantially as set forth.

31. In a receiver for the purpose described, the combination of a printing-drum carrying two lines of type, an impression-roller cooperating with each line, a slide-head, a tongue carried by said slide-head, a polarized relay for operating said tongue, a main shaft, a cam on said shaft for reciprocating said slide-head, and means on said shaft for rotating the polarized relay, substantially as set forth.

32. In a receiver for the purpose described, the combination of a suitable carrier, two lines of type carried thereby, an impression-roller cooperating with each line, a slide-head, a polarized relay which causes the slide-head to actuate either impression-roller, contact-plates, a collecting device cooperating with the contact-plates and connected electrically with

aid relay, and means for simultaneously actuating the slide-bar, carrier and collecting device, substantially as set forth.

53. In a receiver for the purpose described, the combination of a printing-drum carrying two lines of type, an impression-roller cooperating with each drum, means controlled electrically for selecting and operating either of said impression-rollers, a paper strip engaging each impression-roller, feed-rollers for said strips, and means for rotating said feed-rollers and said printing-drum in the same surface speed, substantially as set forth.

54. In an assembly voting apparatus, the combination with a transmitter, of a totalizer electrically connected to and operated from said transmitter and employing a number-disk, means for intermittently feeding said number-disk electrically, a screen, and means for projecting light through the disk and upon the screen, substantially as set forth.

55. In an assembly voting apparatus, the combination with a transmitter, of a totalizer electrically connected to and operated from said transmitter and employing a plurality of number-disks, means for electrically actuating said number-disks, a screen, and means for projecting light through the number-disks and upon the screen, substantially as set forth.

56. In an assembly voting apparatus, the combination with a transmitter, of a totalizer electrically connected to and operated from said transmitter and employing a shaft, means for driving the shaft, a number-disk on the shaft, an escapement-wheel, an escapement for permitting feed movements of said wheel, a magnet for actuating said escapement, a wide tooth on the escapement-wheel, an extension on the escapement, and means for shifting the escapement-wheel and escapement relatively to each other, substantially as set forth.

57. In an assembly voting apparatus, the combination with a transmitter, of a totalizer electrically connected to and operated from said transmitter and employing a shaft, means for driving the shaft, a number-disk on the shaft, an escapement-wheel, an escapement for permitting feed movements of said wheel, a magnet for actuating said escapement, a wide tooth on the escapement-wheel, an extension on the escapement, and means for shifting the escapement-wheel on said shaft, substantially as set forth.

58. In an assembly voting apparatus, the combination with a transmitter, of a totalizer electrically connected to and operated from said transmitter and employing a shaft, means for driving the shaft, a number-disk on the shaft, an escapement-wheel, an escapement for permitting feed movements of said wheel, a magnet for actuating said escapement, a wide tooth on the escapement-wheel, an extension on the escapement, and a magnet for shifting the escapement-wheel on said shaft, substantially as set forth.

59. In an assembly voting apparatus, the combination with a transmitter, of a totalizer electrically connected to and operated from said transmitter and employing a shaft, means for driving the shaft, a number-disk on the shaft, an escapement-wheel, an escapement for permitting feed movements of said wheel, a magnet for actuating said escapement, a wide tooth on the escapement-wheel, an extension on the escapement, a restoring-magnet, an armature for said magnet, a sleeve surrounding the shaft and engaging the escapement-wheel to effect a longitudinal shift thereof, substantially as set forth.

60. In an assembly voting apparatus, the combination with a transmitter, of a totalizer electrically connected to and operated from said transmitter and employing a shaft, means for driving the shaft, a number-disk on the shaft, an escapement-wheel, an escapement for permitting feed movements of said wheel, a magnet for actuating said escapement, a wide tooth on the escapement-wheel, an extension on the escapement, a restoring-magnet, an armature for said magnet, a sleeve surrounding the shaft and engaging the escapement-wheel to effect a longitudinal shift thereof, and stops for limiting the extreme movements of said disk, substantially as set forth.

61. In an assembly voting apparatus, the combination with a transmitter, of a totalizer electrically connected to and operated from said transmitter and employing a shaft, means for driving the shaft, a number-disk on the shaft, an escapement-wheel, an escapement for permitting feed movements of said wheel, a magnet for actuating said escapement, a wide tooth on the escapement-wheel, an extension on the escapement, a restoring-magnet, an armature for said magnet, a sleeve surrounding the shaft and engaging the escapement-wheel to effect a longitudinal shift thereof, stops for limiting the extreme movements of said disk, and a spring for returning the disk to its normal position, substantially as set forth.

62. Means for selecting a plurality of electrical devices arranged in groups, comprising two sets of contact-plates, the plates of one set being connected to the devices of corresponding groups and the plates of the other set being connected to corresponding devices of the several groups, and current-collecting devices cooperating with said contact-plates and operated at different relative speeds, substantially as set forth.

63. Means for selecting a plurality of electrical devices arranged in groups, comprising two sets of contact-plates, the plates of one set being

connected to the devices of corresponding groups and the plates of the other set being connected to corresponding devices of the several groups, current-collecting devices for said contact-plates, and means for moving the current-collecting device of one set at a speed which will carry it into engagement with all the plates of that set while the collecting device of the other set is moved from one plate to the other of that set, substantially as set forth.

64. Apparatus for successively bringing into circuit with a common electrical receiving device a plurality of electrical devices arranged in groups, comprising in combination a plurality of electrical devices arranged in groups, a common receiving electrical device, two sets of contact-plates, the plates of one set being connected to the several groups and the plates of the other set being connected to corresponding devices of the several groups, current-collecting devices cooperating with said contact-plates, and means for operating said current-collecting devices at different relative speeds, substantially as set forth.

65. In an apparatus for ascertaining and registering the sum of an assembly, the combination of a plurality of transmitting circuit-closing devices, a set of contact-plates with which said circuit-closers are connected, a current-collector cooperating with said contact-plates, a magnetic receiver connected to said current-collector, and means controlled by said receiver for effecting a registration of the condition in which the transmitting circuit-closers are placed, substantially as set forth.

66. In an apparatus for ascertaining and registering the sum of an assembly, the combination of a plurality of transmitting circuit-closing devices, a set of contact-plates with which said circuit-closers are connected, a current-collector cooperating with said contact-plates, a magnetic receiver connected to said current-collector, and means controlled by said receiver for effecting a registration of the condition in which the transmitting circuit-closers were placed, substantially as set forth.

67. In an apparatus for ascertaining and registering the sum of an assembly, the combination of a plurality of transmitting circuit-closing devices, a set of contact-plates with which said circuit-closers are connected, a current-collector cooperating with said contact-plates, a magnetic receiver connected to said current-collector, and means controlled by said receiver for effecting a registration of the condition in which the transmitting circuit-closers were placed, and means for effecting a total of the circuit-closers which were moved in one direction and a corresponding total of the circuit-closers which were moved in the opposite direction, substantially as set forth.

68. In an apparatus for ascertaining and registering the sum of an assembly, the combination of a plurality of circuit-closing disks, a pair of contact devices with which each circuit-closing disk cooperates, a source of polarized current for said contacts, a set of contact-plates connected with said circuit-closers, a current-collector cooperating with said plates, an electromagnetic receiving apparatus connected to said current-collector, and means controlled by said receiving apparatus for effecting a registration of the votes, substantially as set forth.

69. In an apparatus for ascertaining and registering the sum of an assembly, the combination of a plurality of circuit-closing disks, a pair of contact devices with which each circuit-closing disk cooperates, a source of polarized current for said contacts, a set of contact-plates connected with said circuit-closers, a current-collector cooperating with said plates, a polarized relay connected to said current-collector, and means controlled by said polarized relay for effecting a registration of the votes, substantially as set forth.

70. In an apparatus for ascertaining and registering the sum of an assembly, the combination of a plurality of circuit-closing disks, a pair of contact devices with which each circuit-closing disk cooperates, a source of polarized current for said contacts, a set of contact-plates connected with said circuit-closers, a current-collector cooperating with said plates, a polarized relay connected to said current-collector, and means controlled by the relay for effecting a printed record of the votes, substantially as set forth.

71. In an apparatus for ascertaining and registering the sum of an assembly, the combination of a plurality of circuit-closing disks, a pair of contact devices with which each circuit-closing disk cooperates, a source of polarized current for said contacts, a set of contact-plates connected with said circuit-closers, a current-collector cooperating with said plates, a polarized relay connected to said current-collector, and means controlled by the relay for effecting a printed record of the votes and simultaneously effecting a totalization of each vote, substantially as set forth.

72. In an apparatus for ascertaining and registering the sum of an assembly, the combination of a plurality of circuit-closing disks, a pair of contact devices cooperating with each disk, a source of polarized current connected to said contact devices, a set of contact-plates connected to said disks, a current-collector cooperating with said plates, a polarized relay connected with said current-collector, means controlled by the relay for effecting a printed record of the votes and for simultaneously effecting a

totalization thereof, and means for simultaneously restoring the totalizing device, substantially as set forth.

73. In an apparatus for ascertaining and registering the sum of an assembly, the combination of a plurality of circuit-closing disks, a pair of contact devices cooperating with each disk, a source of polarized current connected to said contact devices, a set of contact-plates connected to said disks, a current-collector cooperating with said plates, a polarized relay connected with said current-collector, means controlled by the relay for effecting a printed record of the votes and for simultaneously effecting a totalization thereof, means for simultaneously restoring the totalizing device, means for locking the circuit-closing disks in either of their extreme positions, and means for electrically releasing said disks, substantially as set forth.

74. In an apparatus for ascertaining and registering the sum of an assembly, the combination of a plurality of circuit-closing disks, a pair of contact devices cooperating with each disk, a source of polarized current connected to said contact devices, a set of contact-plates connected to said disks, a current-collector cooperating with said plates, a polarized relay connected with said current-collector, means controlled by the relay for effecting a printed record of the votes and for simultaneously effecting a totalization thereof, means for simultaneously restoring the totalizing device, means for locking the circuit-closing disks in either of their extreme positions, and a magnet in circuit between each of the disks and the contact-plates for releasing the disks, substantially as set forth.

701,815. SAND-REEL FOR OIL OR OTHER LIQUIDS. ERIC W. BATES JR. and ANDREW BATES, Bradford, Pa. Filed Mar. 4, 1902. Serial No. 672,904. (No model.)

Claim.—1. In a sand-reel, the combination with a sand-reel shaft, of a friction-wheel comprising radial arms connected by a rim, a series of courses of arc-shaped segmental cuts arranged to break joints and applied to the opposite sides of the rim, the outer course of cuts being of wood and the inner course of compressed paper, substantially as and for the purposes specified.

2. In a sand-reel, the combination with a suitable reel-shaft, of a friction or brake wheel comprising radial arms connected by a rim and provided with ribs which terminate in shoulders on the rim, and a series of courses of arc-shaped segmental cuts applied on the opposite sides of said rim the inner course of the cuts being on the shoulders formed by the ribs of the radial arms, substantially as and for the purposes specified.

3. In a friction-wheel for sand-reels, the combination with a suitable central support of a series of courses of arc-shaped segmental cuts arranged to break joints and applied on opposite sides of said central support, the outer course of said cuts being of wood, and the intermediate course of compressed paper, substantially as and for the purposes specified.

701,816. PLANT-FERTILIZER-DISTRIBUTING RECEPTACLE. JAMES A. BOWMAN, Hot Springs, Ark. Filed Oct. 18, 1901. Serial No. 73,762. (No model.)

Claim.—1. In a plant-fertilizer-distributing receptacle comprising a receptacle having an elongated spout projecting forwardly therefrom adjacent to the bottom of said receptacle, said spout having a valve at its forward end and a spring-actuated rod or stem attached to said valve and extending entirely through the spout and through the receptacle, said rod or stem being provided with a ring or head upon the rear side of the receptacle adjacent to its handle, substantially as shown and described.

2. A plant-fertilizer-distributing receptacle consisting of a receptacle, the upper end of which slopes rearwardly and is provided with a hinged cover, the hinge of said cover being arranged at the forward end, an elongated tapering spout attached to the forward side of the receptacle adjacent to the bottom of the same, a valve adapted to normally close the forward end of said spout, a rod or stem connected to said valve extending entirely through the spout and receptacle, a ring or head arranged upon the rear end of said stem or rod, a coil-spring surrounding the projecting end of the stem or rod, and the spring-actuated rod or stem being attached to the rear side of the receptacle, substantially as shown and described.

701,817. COLLAPSIBLE REEL. FRANK BOWMAN, Boston Harbor, Mass. Filed Aug. 23, 1901. Serial No. 73,077. (No model.)

Claim.—1. A collapsible reel to hold coils of wire and the like, comprising in combination interfoldable supporting members united crosswise by a central vertical pivot-bolt, a plurality of intersecting spider-arms also mounted crosswise on said pivot-bolt above said supporting members, said spider-arms also being interfoldable in a plane parallel with the plane of the supporting members, and a series of supporting arms clamped on said spider-arms and adjustable radially of the reel thereon, substantially as described.

2. A collapsible reel to hold coils of wire and the like, comprising in combination a pair of interfoldable supporting-bars united crosswise on a central vertical pivot-bolt, a pair of intersecting spider-arms also mounted crosswise on said pivot-bolt above and in a plane parallel with the plane of the supporting-bars, said spider-arms being interfoldable to overlap the interfolded supporting-bars longitudinally thereof, and a series of shorter arms adapted to be adjustably secured in either parallel or upstanding relation on said spider-arms, substantially as described.

3. A collapsible reel to hold coils of wire and the like, comprising in combination a pair of interfoldable supporting-bars united crosswise on a central pivot-bolt, a pair of spider-arms mounted crosswise on said pivot-bolt above and in a plane parallel with the plane of the supporting-bars, and a series of angularly-bent shorter arms provided with clamping devices on their opposite ends, whereby they can be adjustably secured in either parallel or upstanding relation on said spider-arms, substantially as described.

4. The heretofore-described reel to hold coils of wire and the like, the same comprising in combination the horizontal supporting-bars 7 and 8 pivotally united by the bolt 11, the spider-arms 12 and 13 also pivotally connected on bolt 11, the cross-block 14, and the angularly-bent arms 17 having clamps 18 and 20 at their opposite ends, whereby they may be secured in either parallel or vertical relation to the arms 12 and 13, substantially as described.

701,818. ARTIFICIAL LIMB. IRVIN R. FENNER and WILLIAM R. FENNER, San Francisco, Cal. Filed Jan. 2, 1902. Serial No. 67,908. (No model.)

Claim.—1. An artificial limb having an upper section formed of a single sheet of metal bent into a frustum of a cone, said sheet being cut out so as to form an upper continuous horizontal band and a middle continuous horizontal band joined by vertical lines, the ends of said bands overlapping and being provided with means for adjustably securing the same together and the lines being secured at their lower ends in the outside of the lower section, and being surrounded by a metallic band around said lower section, substantially as described.

2. An artificial limb having its top section formed of sheet metal in the shape of a frustum of a cone, the lower edge being fixedly secured to the remainder of the limb, and the vertical meeting edges overlapping and being provided with curves of screw-bolts, the bolts on one side being arranged to register with those on the other side whereby said top section may be adjusted, said top section having a single pulley on each side, and a socket provided with means for fixing it around the stump of the limb and having two guide-pulleys on each side, substantially as described.

701,819. PRIMARY BATTERY. BUREN M. FINELL and WILLIAM R. CLYMER, Cleveland, Ohio, assignors to National Carbon Company, Cleveland, Ohio, a Corporation of New Jersey. Filed Oct. 14, 1901. Serial No. 75,588. (No model.)

Claim.—1. In a voltaic cell, in combination, a combined containing vessel and negative electrode, an annular perforated partition within said vessel-electrode mechanically and electrically connected to the bottom thereof, depolarizing material packed in the space between said partition and vessel-electrode, an exciting solution in said vessel, a zinc electrode immersed in said solution, a cover sealed to said vessel, a vent for said vessel above the exciting solution, and means for opening and closing said vent, substantially as specified.

2. In a voltaic cell, in combination, a combined containing vessel and negative electrode made of a suitable metal; a cover sealed to said vessel but having a vent-hole, means for opening and closing said vent-hole, a perforated metallic partition in said vessel mechanically and electrically connected to the bottom thereof, finely-subdivided particles of depolarizing material in the space between said partition and vessel-electrode, an exciting solution in said vessel, a zinc electrode centrally located within said vessel and immersed in said solution and supported but insulated from said cover, substantially as specified.

3. In a voltaic cell, in combination, a combined containing vessel and negative electrode made of a suitable metal, a cover sealed to said vessel but having a vent-hole, means for opening and closing said vent-hole, an annular perforated metallic partition mechanically and electrically connected with the bottom of said vessel, a layer of cloth covering the outer face of said partition, a layer of sand in the bottom of the annular space between said cloth and the vessel-electrode, a layer of finely-subdivided cupric acid packed in said space above said sand, and a seal in said space above said cupric acid, a caustic-soda solution in said vessel-electrode, and a zinc electrode immersed in said solution and supported by but insulated from the cover, substantially as specified.

4. A cylindrical containing vessel made of a suitable metal whereby it also serves as the negative electrode, a cylindrical perforated metallic partition concentrically placed in said vessel and mechanically and electrically connected with the bottom thereof, finely-subdivided depolarizing material packed in the annular space between said partition and vessel, a centrally-placed zinc electrode, and an exciting solution of caustic soda in said vessel, substantially as specified.

5. In a voltaic cell, in combination, a combined containing vessel and negative electrode made of a suitable material, a cover sealed thereto but having a vent-hole, means for opening and closing said vent-hole, a perforated metallic partition secured to the bottom of said vessel, finely-subdivided cupric acid packed in the space between said partition and vessel, an exciting solution in said vessel, a zinc electrode immersed in said solution having a stem which is attached to but insulated from the cover, and an inclined splash-plate secured in said vessel between the cover and top of said perforated partition, substantially as specified.

701,820. COMBINED END-BOARD AND BOOT FOR WAGON. CHARLES FISHER, Lyons, N. Y., assignor of one-half to George A. HERR, Newark, N. Y. Filed Apr. 21, 1902. Serial No. 104,084. (No model.)

Claim.—A combined end-board and end-board for wagon-boxes, comprising a metal plate having upturned opposite sides to pass outside the wagon-box, severed near their ends from the intermediate part of the plate by slots, said intermediate part being bent or rolled to the form of a tube with its convex surface in contact with the wagon-box, a pair of holding joint-straps rigid with the wagon-box having perforated ends projecting through said slots opposite the respective ends of said tube, an axial rod within the tube and passing through the joint-straps, and a notched hanger held pivotally to each upturned side of the plate, and loops on the wagon-box to control the notched hangers, substantially as set forth and shown.

701,821. SMALL ARM. ADOLF FRANK, Hamburg, Germany. Filed Aug. 22, 1901. Serial No. 73,945. (No model.)

Claim.—1. The combination with a spring-actuated hammer and a to-and-fro movable locking-bolt adapted to move said hammer into half-cock position against the stress of its spring when said bolt is moved in one direction; of a trigger and a rear controlled thereby and adapted to engage the hammer and hold it in its said position to admit of the movement of the locking-bolt out of engagement with the hammer and to move the latter into full-cock position by a pull on the trigger, for the purpose set forth.

2. The combination with a spring-actuated hammer and a to-and-fro movable hand-operated locking-bolt adapted to move said hammer into a half-cock position and lock the same against the stress of its spring; of

a spring-actuated trigger and a spring-actuated rear controlled thereby and adapted to engage the hammer and hold it in its said position to admit of the movement of the locking-bolt out of engagement with said hammer and to move the latter into full-cock position by a pull on the trigger and to release it by a further pull on said trigger, for the purpose set forth.

3. The combination with a spring-actuated hammer and a hand-operated locking-bolt adapted when moved in one direction to retract and lock said hammer against the stress of its spring; of a spring-actuated trigger and a spring-actuated rear mounted on said trigger and adapted to engage the hammer when retracted and to release the same by a pull on the trigger against the stress of its spring, for the purpose set forth.

4. In a double-barrel break-down gun, the combination with the hammer and a to-and-fro movable locking-bolt for the barrels, said bolt adapted to move the hammers to a half-cock position against the stress of their springs when moved to unlock the barrels; of a trigger and a rear for each hammer, said rear adapted to engage and lock their respective hammers into their said half-cock position, to admit of the movement of the locking-bolt out of engagement with the hammers and into engagement with the barrels, and then by a pull on the trigger to move said hammers into full-cock position and by a further pull on said triggers to release the hammers, for the purpose set forth.

5. The combination with a spring-actuated hammer, and means for moving the same into half-cock position and again releasing it; of a rear, and a trigger controlling the same, said rear adapted to engage and hold said hammer in its off-cock position, to move said hammer into full-cock position by a pull on the trigger, and to release it by a further pull on said trigger, for the purpose set forth.

701,822. WHEAT-STRAMER. JACOB FRANK, Philadelphia, Pa. Filed Sept. 28, 1901. Serial No. 75,787. (No model.)

Claim.—1. In a grain-straining apparatus, a drum, steaming-chamber within the drum, means for conveying the grain through said chamber, a steam-generator, and means for conveying steam to the steam-chamber and the heat from the steam-generator to the drum, substantially as described.

2. In a grain-straining apparatus, a drum, steaming-chamber within the drum, conveyor within the chamber, apertures between the chamber and drum, a steam-generator, a steam-pipe, leading from the generator to the steaming-chamber, a pipe controlling the steam-pipe communicating with the drum, a burner for the steam-generator, and a water-pipe controlling the steam-generator and communicating with the interior thereof, substantially as described.

3. In a grain-straining apparatus, a drum, steaming-chamber therein, a heater casing, a boiler therein, a steam-pipe leading from the boiler to the steam-chamber, and a pipe leading from the heater-casing to the drum, insulating the steam-pipe, substantially as described.

4. In a grain-straining apparatus, a drum, steaming-chamber within the drum, cover conveyor in the steaming-chamber, shafts journaled in the drum-heads on which the cover conveyors are mounted, gear-wheels connecting the shafts, a pulley on one shaft from which motion is derived from any suitable source, a heating-casing, a boiler within the casing, a burner under the boiler, a feed-water pipe controlling the boiler and communicating with the interior thereof, a steam-pipe connected to the boiler and to one of the steaming-chambers, and a pipe including the steam-pipe, connecting the heating-casing and the drum, whereby steam is conducted to the steaming-chambers and heat is carried to the drum simultaneously, as and for the purpose described.

701,823. GAS-LAMP. LOUIS C. FULMER, Kansas City, Mo. Filed Dec. 24, 1900. Serial No. 69,911. (No model.)

Claim.—1. In a lamp, the combination of a lateral arm, a vertical finger rising therefrom, a sheet-metal strip secured to the finger, and having its upper end bent outwardly and perforated, a crimp or band in said strip below said perforated portion, a vertical perforation through said lateral arm, and a mantle-supporting wire extending through both of said perforations and frictionally engaged by said crimp, substantially as described.

2. In a lamp, a mantle-supporting device comprising, in combination with fingers for guiding the chimney, a sheet-metal strip secured to the outer face of one of the fingers, said strip having an outwardly-projecting perforated ear and a crimp or band below said ear, a lateral extension from the lower end of said finger having a vertical perforation therethrough, and a mantle-supporting wire extending through both of said perforations, substantially as described.

3. A mantle-support for lamps, comprising a central tube 14, a spider mounted thereon, having a radial arm thereon, a vertical finger rising from said arm, a sheet-metal strip secured to the outer face of said finger, a perforated ear extending laterally from said strip, a crimp or band in said strip below said ear, a vertical perforation through said radial arm, and a mantle-supporting wire passing through said perforation and through said perforated ear, and frictionally engaged by said crimp in said sheet-metal strip, substantially as described.

4. In a lamp-burner, a vertical tube, and a tubular wire-glass tip mounted thereon, having its top of greater thickness than its sides, substantially as described.

5. In a lamp-burner, a tubular wire-glass tip having its top formed by overlapping flaps cut from the upper end of the tip, substantially as described.

701,824. VOTING-MACHINE. OTTOMAR A. GATHELL, Columbus, Ohio, assignor to Preston C. Houston, Jamestown, N. Y. Filed July 31, 1901. Serial No. 75,697. (No model.)

Claim.—1. In a voting-machine, the combination with a key-voting mechanism, of mechanism adapted to be operated to deliver a separate paper ballot to the voter, and means for locking the ballot-releasing mechanism if a key is voted, and for locking the key-voting mechanism if the ballot-delivering mechanism is operated, substantially as described.

2. In a voting-machine, the combination of mechanism for voting straight party tickets and upon questions submitted to election, mechanism adapted to be operated to deliver a separate paper ballot to the voter, mechanism permitting voting by those of limited franchise, and means operative by the judges of election for locking out all except the last-named mechanism, substantially as described.

3. In a voting-machine, the combination of mechanism for voting straight party tickets and upon questions submitted to election, mechanism for delivering to the voter a separate paper ballot, and mechanism permitting voting by those of limited franchise, means operative by the judges of election for locking out all the mechanism except the last named, and mechanism for resetting simultaneously all the mechanism, substantially as described.

4. In a voting-machine, the combination of straight-ticket-voting mechanism, a paper-ballot receptacle, a key to be operated to release to the voter a ballot from said receptacle, locking-out devices common to

the straight-ticket-voting mechanism and the ballot-releasing key, substantially as described.

5. In a voting-machine, keys for voting straight tickets, a ballot-receptacle, a drawer therein adapted to be operated to extract a ballot from a package of ballots therein, means for locking said drawer in its closed position, means for locking the same in its open position, combined with a key to be operated to release the drawer, and mechanism for locking out the straight-ticket keys if the ballot-releasing key is operated, substantially as described.

6. In a voting-machine, keys for voting straight tickets, a ballot-receptacle, a drawer therein adapted to extract a paper ballot from a package of ballots in said receptacle, means tending to open said drawer, means for locking said drawer in its closed position, means for locking the same in its open position, combined with a key to be operated to release the drawer and mechanism for locking out the straight-ticket keys if the ballot-releasing key is operated, substantially as described.

7. In a voting-machine, a case, a ballot-receptacle in said case, a drawer adapted to withdraw from the case a ballot from a package of ballots in the receptacle, an adjustable plate for diminishing or increasing the opening and key-operated device for releasing said drawer, combined with key-voting mechanism, and means for locking and releasing said key mechanism common also to the opening device of the drawer in the case through which the ballot is drawn by said drawer, substantially as described.

8. In combination with a voting-machine having voting device provided with means independent of the door for locking them when voted, relative means extending beyond the case operated by the door for resetting the voting device to voting position, a latch having a door permitting ingress or egress of the voter thereto, and a cylinder-cum on said door for operating the relative means for resetting the voting device, substantially as described.

9. In a voting-machine, a plurality of push-keys having notches 12°, a series of cavities 12° and a notch 12°, locking mechanism for said keys comprising expandable blocks to be operated by the keys, and a separate sliding bar arranged to be moved to lock both the voted and unvoted keys, substantially as described.

10. In a voting-machine, a plurality of push-keys, locking mechanism for said keys comprising expandable blocks, a sliding locking-bar supported by one of said blocks, said bar being moved to lock in the voted key and lock out the unvoted key when one of said keys is voted, substantially as described.

701,825. STOVE. HOWARD G. GUNDEL, Erie, Pa. Filed June 12, 1901. Serial No. 63,161. (No model.)

Claim.—1. In a stove, the combination of a lining for a fire-pot having a series of substantially upright air-ducts therein communicating with the fuel-space of the fire-pot; a grate at the bottom of the fire-box; a stove-base below the fire-box comprising an ash-pit and having an air-passage cut therein above the ash-pit; and passages arranged to conduct the delivery of air from the passages in the base to points at the sides and near the bottoms of the air-ducts, said ducts being open at the bottom for the escape of ashes.

ducts, said ducts being open at the bottom for the escape of ashes; and means for controlling said passages.

2. In a stove the combination of the base comprising an ash-pit; a fire-pot above the ash-pit having a lining provided with a series of air-ducts leading into the pot and opening at their bottoms into the ash-pit; and an air-passage cut in the base above the ash-pit and arranged to deliver air to the ash-pit at the sides of the bottoms of the ducts.

3. In a stove, the combination of a lining for a fire-pot having a series of substantially upright air-ducts therein communicating with the fuel-space of the fire-pot; a grate at the bottom of the fire-box; a stove-base below the fire-box comprising an ash-pit and having an air-passage cut therein above the ash-pit; and passages arranged to conduct the delivery of air from the passages in the base to points at the sides and near the bottoms of the air-ducts, said ducts being open at the bottom for the escape of ashes.

701,826. ELEVATOR. HOWARD G. GUNDEL, Erie, Pa. Filed Aug. 28, 1902. Serial No. 728,513. (No model.)

Claim.—1. In an elevator, an endless driving-cable forming two light, two driving-sheaves, one in each of said light and both acting to drive said cable, impelling means for driving said sheaves and means for causing expansion and contraction of at least one sheave.

2. In an elevator, an endless driving-cable forming two light, two sheaves, one in each of said light, a common driving means other than said cable for running said sheaves simultaneously, and means for changing the relative diameters of said sheaves.

3. In an elevator, a counterweight and a traveling part moving in opposition to said counterweight, a block connected with said counterweight and a block connected with said oppositely-moving part; in combination with an endless cable forming two light in said block, a driving-sheave in each light of said cable and means for varying the relative diameters of said sheaves.

4. In an elevator, a counterweight and a traveling part moving in opposition to said counterweight, a block connected with said counterweight and a block connected with said oppositely-moving part; in combination with an endless cable forming two light in said block, a driving-sheave, two expandable sheaves on said shaft, one for each light of cable, and means for changing the relative diameters of said sheaves.

5. In an elevator, a counterweight and a traveling part moving in opposition to said counterweight, a block connected with said counterweight and a block connected with said oppositely-moving part; in combination with an endless cable forming two light in said block, a driving-sheave, two expandable sheaves on said shaft, one for each light of cable, and means for expanding one or the other of said sheaves at will.

6. In an elevator, an endless driving-cable forming two light, two sheaves at least one of which is expandable, both being adapted to run simultaneously, one in each light of said cable, a spring take-up in each light of said cable and means for controlling the expansion of said expandable sheave.

7. In apparatus for producing motion a driving-shaft with two sheaves fast thereon, at least one of which is hollow and is made of resilient material, and said hollow sheave being composed of parallel movable sections, a driving-cable running over both of said sheaves and a cone adapted to extend more or less into said expandable sheave.

8. In apparatus for producing motion a driving-shaft, two hollow sheaves of resilient material made fast thereon, said sheaves being composed of parallel movable sections, a driving-cable passing over both of said sheaves and a double cone centered on said shaft and adapted to slide on said shaft so as to extend more or less into the hollow of either sheave.

9. The combination, with two rotary pulleys, of a cable engaging both pulleys, a device to be driven connected by said cable with both pulleys and tending to be moved thereby respectively in opposite directions, and means for varying the relative diameters of the driving or cable-engaging faces of the two pulleys, thereby controlling the direction and speed of movement of the driven device.

10. The combination, with differential mechanism consisting of a rotary driven element, rotary driving elements, and a cable connecting and engaging the driving and driven elements, the driving elements tending to move the driven element respectively in opposite directions, a motor oppositely connected with the driving elements and driving them at the same angular velocity, and manually-controlled means for controlling the relative peripheral speeds of the cable-engaging faces of the driving elements, thereby controlling the stoppage, direction and speed of the driven element without changing the speed or direction of the motor.

11. The combination, with differential mechanism consisting of a driven pulley, driving-pulley, and a cable connecting and engaging the driving and driven pulleys, the driving-pulley tending to move the driven pulley respectively in opposite directions, a motor, driving connection from the motor to the pulleys, and means for varying the relative peripheral speeds of the driving parts of the driving-pulley, independently of the operative connections between them and the motor, thereby controlling the relative peripheral speeds of the driving-pulleys of the differential mechanism and the stoppage, direction and speed of the driven pulley.

12. The combination, with a shaft and two pulleys driven therefrom of differential mechanism consisting of a driven device a driving-cable connected with the two pulleys, the driven device being adapted to move to take up the excess of length of the driving-cable fed to and from one pulley over that fed to and from the other, a motor adapted to drive the shaft, and means independent of said driving connection for varying the relative peripheral speeds of the driving or cable-engaging faces of the two pulleys.

13. In an apparatus of the character described, the combination with a bodily-movable device, of two rotary drivers, the driving-cables extending around a rotary driving-drum of one of the drivers, thence around the movable device, and thence around the rotary driving-drum of the other driver, driving means for the rotary drivers, the controlling mechanism, and means controlled thereby independent of the driving means to vary the relative peripheral speeds of the rotary drivers, whereby said bodily-movable device may be moved in opposite directions and its direction of travel and rate of speed controlled.

14. In an apparatus of the character described, the combination, with a bodily-movable device, of a rotary shaft, two rotary pulleys driven thereby at the same relative angular velocities, the driving-cables extending around one of said pulleys, thence around the bodily-movable device and thence around the other of said pulleys, the controlling mechanism, and means adapted thereby to vary the relative peripheral speeds of said pulleys whereby said bodily-movable device may be moved in opposite directions and its direction of travel and rate of speed controlled.

15. In an apparatus of the character described, the combination with two rotary pulleys, means for driving them, and driving-cables extending around and adapted to be driven by said pulleys, of a bodily-movable device

with which the driving-cables engage and which is adapted to move to take up the excess of length of the driving-cable fed to and from one pulley over that fed to and from the other, the controlling mechanism, and means, independent of the driving means, adapted by the controlling mechanism to vary relatively the peripheral speeds of the two pulleys, thereby controlling the travel and speed of the bodily-movable device.

16. In an apparatus of the character described, the combination of two rotary pulleys, means for driving them constantly at the same angular velocities, driving-cables extending around and adapted to be driven by said pulleys, bodily-movable devices with which the driving-cables engage, and which are adapted to move oppositely to take up the excess of length of driving-cable fed to and from one pulley over that fed to and from the other, controlling mechanism, and means adapted thereby to vary relatively the peripheral speeds of the cable-engaging faces of the two sheaves, thereby controlling the travel and speed of the said bodily-movable devices.

17. In an apparatus of the character described, in combination, driving-pulleys, cables passing around the same, a motor, driving connection between the motor and the pulleys whereby the same are constantly driven at the same relative angular velocities, the diameters of the driving-faces of said pulleys being capable of being varied with reference to each other, controlling mechanism, and connection between said pulleys and the controlling mechanism whereby the diameters of the driving-faces of said pulleys may be varied with reference to each other by said controlling mechanism, whereby the cables are fed from the pulleys at different relative speeds, and a bodily-movable device adapted to take up the excess of length of cable fed to and from one pulley over that fed to and from the other.

18. In an apparatus of the character described, the combination with two rotary drivers and a bodily-movable device, of the driving-cables connected with the bodily-movable device so as to control the travel back-and-forth movement of the same, the said driving-cables extending around the driving-faces of the two rotary drivers, a motor, a driving connection therefrom to the drivers, the controlling mechanism, and means controlled thereby, and independent of the driving connection, to vary the relative peripheral speeds of the driving-faces of the two rotary drivers, causing the movable device to travel in one direction or the other.

19. In an apparatus of the character described, the combination with two bodily-movable devices, of two driving-pulleys, cables engaging said pulleys and in operative connection with the bodily-movable devices, a rotating shaft, said pulleys being driven constantly at the angular velocity of the shaft, and means to vary the diameters of the driving faces of the pulleys with reference to each other, whereby the movable devices may be fed in opposite directions and at different speeds.

20. In an apparatus of the character described, the combination with two devices to be driven and two traveling sheaves connected respectively to said devices, of two driving-pulleys, a motor, a driving connection from the motor to the pulleys whereby said pulleys are constantly driven at the same relative angular velocities, the diameters of the driving-faces of said pulleys being capable of being varied with reference to each other, controlling mechanism, and connection between said pulleys and the controlling mechanism whereby the relative diameters of the driving-faces of said pulleys may be varied by said controlling mechanism.

21. In an apparatus of the character described, the combination, with two bodily-movable devices, of two rotary drivers, a motor, a driving connection from the motor to the drivers, a driving connection from the rotary drivers to the movable devices, and means to vary the relative peripheral speeds of the driving parts of the rotary drivers without changing their angular velocity.

22. In an elevating apparatus, the combination with two bodily-movable devices, two driving-pulleys, a motor, driving connection from the motor to the pulleys whereby they are driven constantly at the same relative angular velocities, cables connecting the pulleys with the movable devices, and connecting the movable devices with each other, whereby any movement of one movable device will be accomplished during an opposite movement of the other, and means to vary the relative peripheral speeds of the driving-faces of the pulleys, thereby controlling the speed and travel of the bodily-movable devices.

23. In an elevating apparatus, the combination, with two traveling sheaves and two driving-pulleys, of a cable extending from one traveling sheave to one driving-pulley, thence to the other traveling sheave, thence to the other driving-pulley and thence back to the first-mentioned traveling sheave, a motor, a driving connection therefrom to the driving-pulleys, and means to vary the relative diameters of the driving-faces of said pulleys.

24. The combination with a shaft of means for driving said shaft, a pair of sheaves mounted on said shaft, a pair of traveling pulleys, an end

two cable loops around said sheaves and pulleys driven by said sheaves, and means for varying the relative diameter of said sheaves.

701,827. CONTINUOUS AUTOMATIC AIR-BRAKE SYSTEM.
HOWARD L. GARR, Chicago, Kans., assignor of one-half to Louis A. Laughlin, Kansas City, Mo. Filed Nov. 1, 1901. Serial No. 98,758 (No model.)

Claim.—1. In an apparatus of the character described, a valve-controlled connection between the signal-line and the auxiliary reservoir, a connection between the main reservoir and signal-line, a reducing-valve in such connection, a diaphragm on said connection between the reducing-valve and the signal-line, and a connection between said diaphragm and the train-pipe, whereby a reduction of pressure in the latter shall result in the operation of the diaphragm and the passage of air through said connection to the signal-line, substantially as described.

2. In an apparatus of the character described, a valve-controlled connection between the signal-line and the auxiliary reservoir, a connection between the main reservoir and signal-line, embodying a check-valve, and means whereby a suitable decrease of pressure in the train-pipe shall result in the discharge of air through said check-valve and into the signal-line; said check-valve discharging being about equal in volume to that pumped into the main reservoir as said discharge takes place.

3. In an apparatus of the character described, a valve-controlled connection between the signal-line and the auxiliary reservoir, a main auxiliary reservoir, a connection between the main reservoir and said main auxiliary reservoir, a connection between the main auxiliary reservoir and the signal-line, and means whereby a suitable decrease of pressure in the train-pipe shall permit air to pass from the main auxiliary reservoir to the signal-line, substantially as described.

4. In an apparatus of the character described, a valve-controlled connection between the signal-line and the auxiliary reservoir, a main auxiliary reservoir, a connection between the main reservoir and the main auxiliary reservoir, whereby the latter is supplied without robbing the former of the required pressure, a connection between the main auxiliary reservoir and the signal-line, means whereby a reduction in the train-pipe pressure shall result in the passage of air from the main auxiliary reservoir to the signal-line, and means to limit the volume of air passing from the main auxiliary reservoir to the signal-line, substantially as described.

5. In an apparatus of the character described, a valve-controlled connection between the signal-line and the auxiliary reservoir, a main auxiliary reservoir, a connection between the main and main auxiliary reservoirs whereby the latter receives air from the former in volume proportionate to the pump-supply, a connection between the main auxiliary reservoir

and the signal-line, a reducing-valve in such connection, and means also on said connection whereby a suitable reduction of pressure in the train-pipe shall permit air to pass from the main auxiliary reservoir to the signal-line, substantially as described.

6. In an apparatus of the character described, a valve-controlled connection between the signal-line and the auxiliary reservoir; a valve on the signal-line, to offer resistance to the passage of air therein from the main reservoir until an initial pressure in said reservoir, train-pipe, and the auxiliary reservoir has been obtained; a connection between the signal-line and the reservoir-line, the point of connection with the reservoir-line being between the main reservoir and the train-pipe; and means whereby a suitable decrease of pressure in the train-pipe shall permit air to pass through said last-mentioned connection and into the signal-line.

701,828. CONTINUOUS AUTOMATIC AIR-BRAKE SYSTEM.
HOWARD L. GARR, Chicago, Kans., assignor of one-half to Louis A. Laughlin, Kansas City, Mo. Filed Jan. 10, 1902. Serial No. 98,148 (No model.)

Claim.—1. The combination is an automatic air-brake apparatus, of the triple valve provided with an opening and a port, the former communicating with the triple-valve-piston chamber at the train-pipe side of the piston thereof in its emergency position, and the latter with said chamber at a point between the feed-groove thereof and the service position of the piston, and a feed-valve attachment connected to said opening and port, and adapted when the train-pipe pressure falls below a predetermined standard but still exceeds that of the auxiliary reservoir to receive train-pipe air and deliver it to the said piston-chamber through said port.

2. The combination is an automatic air-brake apparatus, of the triple valve provided with an opening and a port, the former communicating with the triple-valve-piston chamber at the train-pipe side of the piston thereof in its emergency position, and the latter with said chamber at a point between the feed-groove thereof and the service position of the piston, a feed-valve attachment connected to said opening and port, and adapted when the train-pipe pressure falls below a predetermined standard but still exceeds that of the auxiliary reservoir to receive train-pipe air and deliver it to the said piston-chamber through said port, and means for reinforcing the train-pipe pressure in proportion to the loss by leakage.

3. The combination is an automatic air-brake apparatus, of the triple valve provided with an opening and a port, the former communicating with the triple-valve-piston chamber at the train-pipe side of the piston thereof in its emergency position, and the latter with said chamber at a point between the feed-groove thereof and the service position of the piston, a feed-valve attachment connected to said opening and port, and adapted when train-pipe pressure falls below a predetermined standard but still exceeds that of the auxiliary reservoir to receive train-pipe air and deliver it to said piston-chamber through said port, and a reducing-valve in communication with the main reservoir and the train-pipe and adapted to automatically reinforce the latter from the former to compensate for fall of pressure occasioned in the train-pipe by leakage.

4. The combination is an automatic air-brake apparatus, of the triple valve provided with an opening and a port, the former communicating with the triple-valve-piston chamber at the train-pipe side of the piston thereof in its emergency position, and the latter with said chamber at a point between the feed-groove thereof and the service position of the piston, and a feed-valve attachment connected to said opening and port, and adapted when the train-pipe pressure falls below a predetermined standard but still exceeds that of the auxiliary reservoir to receive train-pipe air and deliver it to the said piston-chamber through said port, and adapted when the train-pipe pressure rises above such predetermined pressure to close communication between the train-pipe and said port.

5. The combination is an automatic air-brake apparatus, of the triple valve provided with an opening and a port, the former communicating with the triple-valve-piston chamber at the train-pipe side of the piston thereof in its emergency position, and the latter with said chamber at a point between the feed-groove thereof and the service position of the piston, and a feed-valve attachment connected to said opening and port, and adapted when the train-pipe pressure falls below a predetermined standard but still exceeds that of the auxiliary reservoir to receive train-pipe air and deliver it to the said piston-chamber through said port, and means to automatically close communication between the train-pipe and said port when the pressure in the auxiliary reservoir exceeds that of the train-pipe.

6. The combination with an automatic air-brake apparatus, of a feed-valve attachment having a supply-port, and a discharge-port, in communication with the triple-valve-piston chamber, and provided with a valve adapted when the pressure of the train-pipe falls below a given standard to permit train-pipe air to pass and enter the triple-valve-piston chamber, and to close such line of communication when the train-pipe pressure rises above such predetermined standard; said attachment also comprising a piston controlling the discharge-port, and adapted to be actuated by air-pressure before the closing of said valve occurs, and a check-valve adapted to be seated by back pressure in said discharge-port, substantially as described.

701,829. AUTOMATIC SELF-INFLATING LIFE-PRESERVER.
JAMES GRAMER, Cincinnati, and ROBERT R. TAYLOR, Stirling, Scotland. Filed Dec. 14, 1901. Serial No. 98,451. (No model.)

Claim.—1. Improved apparatus for automatically inflating a life-belt garment or appliance, comprising a spring arranged in a casing having an outlet connected to the inlet part of the life-belt, the spring having a head part bearing against the rim or edge of the barrel of the casing, a rod extending through the casing and connected to the spring and to the inner part of a hobbin-piece composed of outer and inner parts hailing against each other, the outer part having a head bearing against the other rim or edge of the casing-barrel, holes or inlet-passages being formed through the hobbin-piece and through that portion of the casing enclosing it, a strip or roll of paper being fixed to the two parts of the hobbin-piece, a piston fixed to the rod and fitting the interior of the casing, a spring-controlled inlet-valve furnished with a push-handle and working on a nut arranged on a cap-piece fixed to the hobbin end of the casing, a receptacle containing gas-yielding materials, the said receptacle being inclosed with the helical spring in the casing and mechanism adapted to be acted on by the release of the spring to free the contents of the receptacle, substantially as described.

2. Improved apparatus for automatically inflating a life-belt, garment or appliance comprising in combination a helical spring extending within a casing having an outlet connected to the inlet part of the life-belt, the spring having a head part bearing against the rim or edge of the casing-barrel, a rod extending through the casing and connected to the spring and, through a hobbin-piece, to a strip or roll of paper, a piston fixed to the rod and fitting the interior of the casing, a spring-controlled inlet-valve fixed to the casing, with means for operating on a nut in a vessel fixed in the casing and containing materials for producing the gas for inflating the life-belt, substantially as hereinbefore described.

3. Improved apparatus for automatically inflating a life-belt, garment or appliance, comprising in combination a helical spring extending within a casing having an outlet connected to the inlet part of the life-belt, the spring having a head part bearing against the rim or edge of the casing-barrel, a rod extending through the casing and connected to the spring and, through a hobbin-piece, to a strip or roll of paper, a piston fixed to the rod and fitting the interior of the casing, a spring-controlled inlet-valve fixed to the casing, with means for operating on a nut in a vessel fixed in the casing and containing materials for producing the gas for inflating the life-belt, substantially as hereinbefore described.

4. Improved apparatus for automatically inflating a life-belt, garment or appliance, comprising in combination a helical spring extending within a casing having an outlet connected to the inlet part of the life-belt, the spring having a head part bearing against the rim or edge of the casing-barrel, a rod extending through the casing and connected to the spring and to the inner part of a hobbin-piece composed of outer and inner parts hailing against each other, the outer part having a head bearing against the other rim or edge of the casing-barrel, holes or inlet-passages being formed through the hobbin-piece and through that portion of the casing enclosing it, a strip or roll of paper being fixed to the two parts of the hobbin-piece, a piston fixed to the rod and fitting the interior of the casing, a spring-controlled inlet-valve furnished with a push-handle and working on a nut arranged on a cap-piece fixed to the hobbin end of the casing, a receptacle containing gas-yielding materials, the said receptacle being inclosed with the helical spring in the casing and mechanism adapted to be acted on by the release of the spring to free the contents of the receptacle, substantially as hereinbefore described.

5. Improved apparatus for automatically inflating a life-belt, garment or appliance, comprising in combination a helical spring extending within a casing having an outlet connected to the inlet part of the life-belt, the spring having a head part bearing against the rim or edge of the casing-barrel, a rod extending through the casing and connected to the spring and to the inner part of a hobbin-piece composed of outer and inner parts hailing against each other, the outer part having a head bearing against the other rim or edge of the casing-barrel, holes or inlet-passages being formed through the hobbin-piece and through that portion of the casing enclosing it, a strip or roll of paper being fixed to the two parts of the hobbin-piece, a piston fixed to the rod and fitting the interior of the casing, a spring-controlled inlet-valve furnished with a push-handle and working on a nut arranged on a cap-piece fixed to the hobbin end of the casing, a receptacle containing gas-yielding materials, the said receptacle being inclosed with the helical spring in the casing and mechanism adapted to be acted on by the release of the spring to free the contents of the receptacle, substantially as described.

701,830. HOE. GEORGE H. UNRAVE, Wellington, New Zealand. Filed May 7, 1901. Serial No. 98,112. (No model.)

Claim.—1. A hoe having its blade inclined to the axis of the handle which latter is cut so that its axis will cut the cutting edge of the blade nearer to the front end 3 of the blade than to the rear end and an upturned leg 5 at the rear end of the blade extending in a plane converging with the axial plane of the handle, substantially as described.

2. In a hoe, barbs formed on the edges of the socket in combination with a ring for forcing the barbs into the handle, substantially as set forth herein.

3. In a hoe having its blade set at an angle, in combination, a socket placed so that its axis will cut the cutting edge nearer to the front end 3 of the blade than to the rear end, an ear on the rear point of the blade, barbs on the edges of the socket, and a securing-ring for forcing the barbs into the handle, substantially as set forth herein.

701,831. MILK-PAIL. JOHN GRAYSON, Scottville, Mich. Filed Mar. 18, 1902. Serial No. 98,794. (No model.)

Claim.—The combination with a pail-top provided with an opening and with a neck surrounding said opening, a partition extending across the top to form a trap or basin, and two sets of studs, one set being arranged in a plane above the other and each set projecting inwardly from the sides of the neck, of a strainer, the lower end of which fits upon the top and abuts against the partition, and the sides of which engage one set of studs to hold the strainer in an inclined position, a shield covering a portion of the neck and extending over the strainer and having notches to engage one set of studs, and a hook and staple for connecting the opposite edge of the strainer to the neck, substantially as set forth.

701,881.

701,882. SWAN-HOOK. James Swan, Clinton, N. Y., assignor to Covert Manufacturing Company, Watervliet, N. Y., a Corporation of New York. Filed Dec. 26, 1901. Serial No. 57,767. (No model.)

Claim.—A snap-hook of the character described comprising a hook portion, and a keeper portion pivoted thereto formed with continuous unbroken depending sides embracing the shank of the hook, and having continuous downwardly and rearwardly inclined forward edges extending from the extreme upper forward end thereof, substantially as described.

701,888. WANDERLAND. Louis H. Wanderland, Cleveland, Ohio. Filed Oct. 5, 1901. Serial No. 77,008. (No model.)

Claim.—1. As a new article of manufacture, a strip of rubber having a surface grooved longitudinally and a ribbon or strip of goods secured thereto and projecting from one edge thereof, the said parts adapted to form the inner and outer portions of a waistband, substantially as described.

2. A waistband for a lady's skirt consisting of a narrow strip of yielding material having longitudinal grooves on one face and being smooth on the other face, combined with a ribbon parallel with the band, and having one edge overlapping the edge of the band on the smooth face, said ribbon being secured to the band by stitches lying within one of the grooves of the band, substantially as described.

3. A lady's skirt having at the upper end a waistband on both the inner and outer sides of the skirt, the band on the inner side being a longitudinally-grooved piece of rubber, the band on the outer side being a ribbon secured to the back side of the rubber and hanging over the upper edge of the skirt and downward along its outer side, substantially as described.

4. A waistband for a lady's skirt consisting of a strip of yielding and flexible material having its inner surface grooved longitudinally, combined with one or more retaining-pieces having a corresponding surface adapted to interfit with the band, whereby material as a skirt-waist may be clamped between them, substantially as described.

5. A waistband having its inner surface composed of longitudinal projections and grooves, combined with a pad having corresponding projections and grooves, said pad being considerably wider than the band whereby it presents a choice of positions for the band, substantially as described.

701,884. DEVICE FOR STRIPPING TOBACCO FROM LATH. PAUL H. GULLERMAN, Oshkosh, Wis. Filed Mar. 28, 1902. Serial No. 100,587. (No model.)

Claim.—1. In a device for stripping tobacco from lath, a standard having a slot to receive the lath, and an apron at one side of the standard

and forming a support for the lath and tobacco, said apron being reversible to admit either of the right-hand or the left-hand use of the device, substantially as specified.

2. In a device for stripping tobacco from lath, a standard having a slot to receive the lath upon which the tobacco-plants are strung, and a flexible apron at one side of the standard and reinforced at intervals by ribs, and means for supporting said apron, substantially as set forth.

3. In a device for stripping tobacco from lath, a standard having a slot for the reception of the lath containing the tobacco, an apron for supporting the lath and tobacco at one side of the standard and reversible so as to extend from either side of the stand, and an apron-support detachably fitted to the stand and adapted to project from either side thereof to support the apron in either of its extreme positions, substantially as set forth.

4. In a device for stripping tobacco from lath, a standard having a slot to receive the lath containing the tobacco, an apron for supporting the lath and tobacco, and a guard at the end of the apron adjacent to the slotted standard, substantially as set forth.

5. In a device for stripping tobacco from lath, a standard having a slot to receive the lath containing the tobacco, a support projected laterally from the stand receiving the slotted standard, an apron of flexible material resting upon said support, and means for stretching the apron and connecting it to the outer end of said support, substantially as specified.

6. In a device for stripping tobacco from lath, comprising a stand, hand and tail standards projected upward from the stand, the hand-standard having a vertical slot in its upper end, a roller journaled between the said standards, an apron attached at its inner edge to said roller and reversible so as to project from either side of the stand, and bars supporting the apron and adapted to be fitted to the stand so as to project from either side thereof, substantially as described.

701,885. DEVICE FOR DRAWING LIQUIDS. LOUIS H. WANDERLAND, San Francisco, Cal., assignor to American Patent Company, San Francisco, Cal., a Corporation of California. Filed Feb. 10, 1902. Serial No. 98,208. (No model.)

Claim.—1. A device for drawing liquids, consisting of a bung having a passage communicating with the liquid-receptacle, a valve controlling said passage, and having a stem mounted in said bung and adapted to operate the valve, a plate to be applied to the outer face of the bung, a flange connection carried by said plate, and adapted to form communication with the bung-passage, and an independent key carried by said plate, and adapted to operate the valve-stem.

2. A device for drawing liquids, consisting of a bung having a passage communicating with the liquid-receptacle, a valve controlling said passage and having a stem mounted relatively in the bung and adapted by its axial movement to operate the valve, a plate to be applied to the outer face of the bung, a flange connection carried by said plate and adapted to form communication with the bung-passage, and a key carried by and relatively mounted in said plate, and adapted to connect with and to operate the valve-stem.

3. A device for drawing liquids, consisting of a bung having a passage communicating with the liquid-receptacle, a valve controlling said passage and having a stem mounted relatively in the bung and adapted to operate the valve, a plate to be applied to the outer face of the bung, a flange connection carried by said plate, and adapted to form communication with the bung-passage, and a key carried by and relatively mounted in said plate, and adapted to connect with and to operate the valve-stem.

of said passage, a stem relatively mounted in the bung, and carrying the valve upon its inner end, a plate to be applied to the outer face of the bung, a flange connection carried by said plate and adapted to form communication with the bung-passage, and a key carried by and relatively mounted in said plate, and adapted to connect with and to operate the valve-stem.

4. A device for drawing liquids, consisting of a bung having a passage communicating with the liquid-receptacle, a valve controlling said passage and having a stem relatively mounted in said bung and adapted to operate the valve, a plate to be applied to the outer face of the bung, a flange connection carried by said plate, and adapted to form communication with the bung-passage, a key carried by and relatively mounted in said plate and adapted to connect with and to operate the valve-stem, and suitable locking connections between the bung and the key, adapted to be operated by the turning of the key while operating the valve.

5. A device for drawing liquids, consisting of a bung having a passage communicating with the liquid-receptacle, a valve controlling said passage and having a stem mounted relatively in the bung, a plate to be applied to the outer face of the bung, a flange connection carried by said plate, and adapted to form communication with the bung-passage, a key carried by and relatively mounted in said plate independently of the flange connection, and adapted to connect with and to operate the valve-stem, and an operating-handle on said key disposed to connect with the flange connection at its limits of movement, whereby the limits of the throw of the valve are defined.

6. A device for drawing liquids, consisting of a bung having a passage communicating with the liquid-receptacle, a valve controlling said passage and having a stem mounted relatively in the bung, a plate to be applied to the outer face of the bung, a flange connection carried by said plate, and adapted to form communication with the bung-passage, a key carried by and relatively mounted in said plate independently of the flange connection, and adapted to connect with and to operate the valve-stem, an operating-handle on said key disposed to connect with the flange connection at its limits of movement, whereby the limits of the throw of the valve are defined, and suitable locking connections between the bung and the key, adapted to be operated by the turning of the key while operating the valve.

7. A device for drawing liquids, consisting of a bung having a passage communicating with the liquid-receptacle, a valve controlling said passage, and having a stem mounted in said bung, a plate to be applied to the outer face of the bung, a flange connection carried by the plate and adapted to form communication with the bung-passage, a key carried by and relatively mounted in the plate independently of and exterior to the flange connection and adapted to connect with and to operate the valve-stem, said key having locking devices to engage the bung, and a handle-lever on the outer end of the key to operate it, said lever being so disposed relatively to the flange connection that its limits of movement are defined by its contact on either side of its center of movement with said flange connection.

8. A device for drawing liquids, consisting of a bung having a passage communicating with the liquid-receptacle, a valve controlling said passage and having a stem mounted in said bung and adapted to operate the valve, a plate to be applied to the outer face of the bung, a sleeve carried by the plate and adapted to form communication with the bung-passage, a dip-pipe carried by said sleeve, and adapted to pass through the bung-passage into the liquid-receptacle when the valve controlling said passage is open, and a key carried by said plate and adapted to operate the valve-stem.

9. A device for drawing liquids, consisting of a bung having a passage communicating with the liquid-receptacle, a valve controlling said passage and having a stem relatively mounted in said bung and adapted to operate the valve, a plate to be applied to the outer face of the bung, a sleeve carried by the plate and adapted to form communication with the bung-passage, a dip-pipe carried by said sleeve and adapted to pass through the bung-passage into the liquid-receptacle when the valve controlling said passage is open, and a key carried by and relatively mounted in said plate and adapted to lock the plate to the bung and to connect with and to operate the valve-stem.

10. A device for drawing liquids, consisting of a bung having a passage communicating with the liquid-receptacle, a valve controlling said passage and having a stem relatively mounted in said bung and adapted to operate the valve, a plate to be applied to the outer face of the bung, a sleeve carried by the plate and adapted to form communication with the bung-passage, a branch for an air-supply connection opening into said sleeve whereby air may be forced through the bung-passage when opened, a dip-pipe carried by the sleeve and adapted to pass through the bung-passage into the liquid-receptacle when the valve controlling said passage is open, and a key carried by and relatively mounted in said plate and

adapted to lock the plate to the bung and to connect with and to operate the valve-stem.

11. A device for drawing liquids, consisting of a bung having a passage communicating with the liquid-receptacle, a valve controlling said passage and having a stem relatively mounted in said bung and adapted to operate the valve, a plate to be applied to the outer face of the bung, a sleeve carried by the plate and adapted to form communication with the bung-passage, a branch for an air-supply connection opening into said sleeve, a dip-pipe carried by the sleeve and adapted to pass through the bung-passage into the liquid-receptacle when the valve controlling said passage is open, said dip-pipe having an exterior diameter sufficiently smaller than the interior diameter of sleeve and passage, to permit the air to pass in around it, to the liquid-receptacle, and a key carried by and relatively mounted in said plate and adapted to lock the plate to the bung and to connect with and to operate the valve-stem.

12. A device for drawing liquids, consisting of a bung having a passage communicating with the liquid-receptacle, a valve controlling said passage and having a stem relatively mounted in said bung and adapted to operate the valve, a plate to be applied to the outer face of the bung, a sleeve carried by the plate and adapted to form communication with the bung-passage, a branch for an air-supply connection opening into said sleeve, a dip-pipe carried by the sleeve and adapted to pass through the bung-passage into the liquid-receptacle when the valve controlling said passage is open, said dip-pipe having an exterior diameter sufficiently smaller than the interior diameter of sleeve and passage to permit the air to pass in around it, to the liquid-receptacle, an independent key relatively mounted in said plate and adapted to lock the plate to the bung and to connect with and to operate the valve-stem, and a handle on the exterior end of the key adapted to connect with the sleeve on either side of the center of movement to define its limits in either direction.

701,886. FURROW OPENING AND COVERING ATTACHMENT FOR PLANTERS. WILLIAM A. HANSEN, Glendale, S. C. Filed Jan. 8, 1902. Serial No. 98,209. (No model.)

Claim.—1. In a planter, the combination of a furrow-opener, standard-arm to which said furrow-opener is secured, the upper portions of said standard-arm being laterally offset, brace-bars in rear of the standard-arm and connected thereto and coverer-arms disposed between said brace-bars and the laterally offset upper portions of the standard-arm, the latter and the coverer-arms being attached to the frame of the planter, substantially as described.

2. In a planter, the combination of a furrow-opener, standard-arm to which said furrow-opener is secured, the upper portions of said standard-arm being laterally offset and secured to the side of the planter, brace-bars in rear of the standard-arm and secured to the lower ends thereof and to the planter, and spring coverer-arms having their front ends attached to the planter, the said spring coverer-arms being disposed between the brace-bars and the laterally offset upper portions of the standard-arm, and thereby adapted to play vertically between them, the brace-bars and standard-arm preventing lateral displacement of the coverer-arms, substantially as described.

701,887. CURTAIN FOR CARRIAGES. GEORGE E. HANSEN, New York, Conn. Filed Aug. 8, 1901. Serial No. 71,261. (No model.)

Claim.—In combination with a carriage-top, a side article, means for attaching said article to the said carriage-top at stated points, and means for preventing the sagging of said article between the said points

of attachment, consisting of metallic strips formed with spurs that are bent and clamped upon the curtain, as set forth, and whose projecting end portion is bent and clamped over the edge of said curtain, substantially as specified.

701,888. ELECTRIC MOTOR. CARTER R. HANSEN, Schenectady, N. Y., assignor to General Electric Company, a Corporation of New York. Filed Oct. 20, 1901. Serial No. 20,000. (No model.)

Claim.—1. In an electric motor, the combination of a field-winding, a conductor having a negative temperature coefficient in series with said winding, and an armature connected about said field-winding and conductor.

2. In an electric motor, the combination of a field-winding and an armature connected in parallel with each other, and means for causing the drop of potential in the field-circuit to be less than proportional to the current flowing therein.

3. In an electric motor, the combination of a motive element in which the torque is produced by the mutual interaction of currents in parallel-connected circuits, and means for causing the resistance of one of said circuits to change upon variation of current in the motor at a rate different from the rate of change of the resistance in the other circuit.

4. In an electric motor, the combination of a field-winding and an armature connected in parallel relation with each other and adapted to be connected in circuit with one of the mains of an electric system, and means for causing the field-winding circuit to be of higher resistance with small currents than with large currents passing therein.

5. In an electric motor, the combination of a field-winding and an armature in parallel-connected circuits, and means for causing the resistance of one of said circuits to be greater when carrying small currents than when carrying larger currents.

6. In an electric motor, the combination of a fixed member, a relatively movable member, connections whereby current flowing in the motor produces torque of the movable member, and a resistance changing with temperature adjusted to change the law of said torque with change in the quantity measured.

701,889. ROTARY ENGINE. FRANK A. BRADSHAW, Lafayette, Ind., assignor of one-half to Leo Pettibone, Norman Pettibone, Julius Pettibone, and Max Pettibone, Lafayette, Ind. Filed Nov. 15, 1900. Serial No. 34,578. (No model.)

Claim.—1. In an engine of the class described, the combination of a casing having an operating-chamber and inlet and outlet passages therefor, a piston rotating in said chamber provided with one or more steam-pockets in the periphery thereof arranged to cover and uncover the inlet-opening and thereby govern the admission of motive fluid, a slidable cut-off valve in each pocket, and rack-and-pinion mechanism for operating said valves, substantially as described.

2. In an engine of the class described, the combination of a casing having an operating-chamber and inlet and outlet passages therefor, a piston rotating in said chamber and provided with one or more steam-pockets in the periphery thereof arranged to cover and uncover the inlet and thereby govern the admission of motive fluid, a slidable cut-off valve in each pocket, rack mechanism on the pocket-wall and on the valve, a spur-pinion engaging both racks to multiply the movement of the valve, and rod-and-lever mechanism arranged to operate the pinion, substantially as described.

3. In an engine of the class described, the combination of a cylinder-casing having an operating-chamber and inlet and outlet passages therefor, an inwardly-projecting banking secured to and forming a part of the casing through which the inlet-opening extends and provided with curved ends which form a part of the walls of the operating-chamber and through which banking the inlet-opening extends, a rotatable piston mounted in each chamber and provided with longitudinal wing-grooves, wing mechanism in each of said grooves provided with a packing in the outer edge thereof consisting of a strip arranged in the bottom thereof provided with a cylindrical contacting surface, and a plurality of longitudinal strips arranged thereon capable of adjusting themselves automatically to the surface of the cylinder, substantially as described.

4. In an engine of the class described, the combination of a cylinder-casing having an operating-chamber and inlet and outlet passages therefor, an inwardly-projecting banking secured to the casing provided with curved ends which form a part of the walls of the operating-chamber and through which banking the inlet-opening extends, a rotatable piston mounted in each chamber and provided with longitudinal wing-grooves diametrically opposite to each other, a wing in each of said grooves connected together across the diameter of the piston and each having a longitudinal packing-groove in the outer edge thereof, a semi-cylindrical strip arranged in the bottom of the packing-groove of each wing, a plurality of strips laid on edge to contact with each other and resting upon the upper surface of the semi-cylindrical strip forming a packing which automatically adjusts itself to the surface of the cylinder, and spring mechanism inserted between the lower side of the wings and the bottom of the wing-grooves in the piston to form a cushion for each wing, substantially as described.

5. In an engine of the class described, the combination of a base portion, a cylinder secured thereto provided with a head at each end thereof having stuffing-boxes thereon, a piston rotatably mounted in the cylinder and having its shaft extending out through the stuffing-boxes of the cylinder-heads, and piston-heads secured adjacent to each end of the piston made in two parts and provided with packing-rings 22 between each part to confine the motive fluid between them, substantially as described.

701,840. MANUFACTURE OF SPHERICAL MAPS. HENRI HENRIKSEN and ALBERT FATHNER, Brussels, Belgium. Filed Nov. 15, 1899. Serial No. 35,573. (No model.)

Claim.—The herein-described process of constructing a spherical chart of a portion of the earth's surface, consisting of first printing a distorted representation of the chart on a flat surface, then embossing said flat surface so as to produce a surface of a sphere corresponding to the curvature of the earth and causing said distortion to be rectified in the step of embossing to produce a true chart of the said portion of the earth's surface, substantially as described.

701,841. ELECTRIC MOTOR. ALBERT R. BRADSHAW, Chicago, Ill. Filed July 15, 1901. Serial No. 35,574. (No model.)

Claim.—1. In an electric motor, the combination of a rotary armature, a drive-shaft rotating therewith, a pinion on each end of said shaft and an annular driven member provided with duplex annular racks respectively engaged with said pinions in diametrically opposite relation,

whereby the driving moment of the motor is simultaneously imparted to said driven element through both pinions.

2. In an electric motor, the combination of a main drive-shaft, an armature mounted thereon, a pinion upon said shaft at each side of said armature, and a driven member provided with duplex annular racks arranged to encircle said armature; said racks being severally engaged with the respective pinions of the armature-shaft in diametrically opposite relation to each other whereby the driving moment of the motor is simultaneously imparted to said driven element through both pinions.

3. In an electric motor, the combination of a relatively stationary frame, a main drive-shaft journaled in said frame and provided with a pair of driving-pinions, an armature mounted upon said drive-shaft between said pinions, a series of field-pieces upon said frame in co-operative relation to said armature, and a driven member comprising duplex parallel annular racks encircling said armature exteriorly of the stationary frame, and having its racks operatively engaged with the respective pinions of the drive-shaft in diametrically opposite relation whereby the driving moment of the armature is imparted to the driven member through both pinions simultaneously and in the same direction.

4. In an electric motor, the combination of a relatively stationary frame, constituting an armature-bearing, a main drive-shaft journaled in said frame and provided with a pair of driving-pinions, an armature mounted upon said drive-shaft between said pinions, a series of field-pieces upon said frame in co-operative relation to said armature, and a driven member comprising duplex parallel annular racks encircling said armature exteriorly of the stationary frame, and having its racks operatively engaged with the respective pinions of the drive-shaft in diametrically opposite relation whereby the driving moment of the armature is imparted to the driven member through both pinions simultaneously and in the same direction.

5. In an electric motor, the combination of a relatively stationary main frame provided with bearing-supports, a main drive-shaft journaled in said frame and provided with a pair of driving-pinions, an armature mounted upon said drive-shaft between said pinions, a series of field-pieces upon said frame in co-operative relation to said armature, and an outer driven member operatively engaged with the bearing-supports of the relatively stationary frame comprising duplex parallel annular racks encircling said armature exteriorly of the stationary frame, and having its racks operatively engaged with the respective pinions of the drive-shaft in diametrically opposite relation whereby the driving moment of the armature is imparted to the driven member through both pinions simultaneously and in the same direction.

6. In an electric motor, the combination of a relatively stationary frame provided with integral oppositely-disposed external projections constituting journals, a main drive-shaft journaled in said frame and provided with a pair of driving-pinions, an armature mounted upon said drive-shaft between said pinions, a series of field-pieces upon said frame in co-operative relation to said armature, and an outer driven member journaled upon said journal projections of the main frame, comprising duplex, parallel, annular racks encircling said armature exteriorly of the stationary frame, and having its racks operatively engaged with the respective pinions of the drive-shaft in diametrically opposite relation whereby the driving moment of the armature is imparted to the driven member through both pinions simultaneously and in the same direction.

7. In an electric motor, the combination of a relatively stationary frame provided with integral oppositely-disposed external projections constituting journals, a main drive-shaft journaled in said frame and provided with a pair of driving-pinions, an armature mounted upon said drive-shaft between said pinions, a series of field-pieces upon said frame in co-operative relation to said armature, and an outer driven member journaled upon said journal projections of the main frame, comprising duplex, parallel, annular racks encircling said armature exteriorly of the stationary frame,

and having its racks operatively engaged with the respective pinions of the drive-shaft in diametrically opposite relation whereby the driving moment of the armature is imparted to the driven member through both pinions simultaneously and in the same direction.

8. In an electric motor, the combination of a relatively stationary motor-casing constituting a substantially complete enclosure, a series of field-magnets arranged upon the interior of said casing, an armature journaled within the casing and a commutator mechanism mounted upon the interior of the casing at one end of said armature, that portion of the wall of the casing which supports the commutator mechanism being made in the form of a removable end cap through which the motor mechanism is insertible and removable, substantially as described.

9. In combination with a wheel, means for propelling the same comprising an annular double driving-rack mounted concentrically with the axis of rotation of said wheel, a drive-shaft arranged diametrically of said rack and provided at each end with a driving-pinion engaged with the rack, and an armature arranged to rotate said drive-shaft.

10. In combination with a wheel having a hollow shell-like hub, a double driving-rack mounted within said hub concentrically with the axis of rotation of the wheel, a drive-shaft arranged diametrically of said rack and provided at each end with a driving-pinion engaged with the rack, a motor-armature mounted upon said drive-shaft within the hub, field-magnets supported upon the wheel in co-operative relation with said armature, and means for supplying electric current to said motor.

11. In combination with a wheel having a hollow shell-like hub, a double driving-rack mounted within said hub concentrically with the axis of rotation of the wheel, a drive-shaft arranged diametrically of said rack and provided at each end with a driving-pinion engaged with the rack, a motor-armature mounted upon said drive-shaft within the hub, field-magnets supported upon the wheel in co-operative relation with said armature, and means for supplying electric current to said motor.

12. In combination with a wheel, having a hollow shell-like hub, means for propelling the same comprising an annular double rack mounted upon the interior of the hub concentrically with the axis of rotation of the latter, a drive-shaft arranged to extend diametrically and diagonally across said annular rack and provided at each end with a driving-pinion engaged with the latter, an armature mounted rigidly upon said drive-shaft, a motor-casing inclosing said armature within the hub-shell and supporting a series of field-magnets in co-operative relation to the armature, said armature-casing being rigidly secured to the interior of the hub, armature-shaft bearings formed in each end of said armature-casing, a commutator-hub mounted upon said armature-shaft adjacent to one of the end walls of the casing, commutator-brushes supported upon the end wall and operatively engaging said commutator, and electrical connections connected with the windings of the field-magnets and commutator-brushes respectively and extending out of the wheel-hub through a non-rotated part of, or upon the wheel-axis, as and for the purpose set forth.

701,842. PROCESS OF MAKING RUBBER TIRES. ALBERT T. HOLT, Springfield, Ohio. Filed Oct. 7, 1901. Serial No. 77,515. (No specimen.)

Claim.—1. The herein-described process of making rubber tires, which consists in subjecting the rubber to heat and pressure in a mold-cavity having the shape of the complete tire, the widest point thereof lying inward from a relatively constricted mouth, and withdrawing the vulcanized tire through said constricted mouth by compressing the wider portions of the body thereof, substantially as described.

2. The herein-described process of making rubber tires, which consists in subjecting the rubber to heat and pressure in a mold-cavity having the shape of the complete tire, the widest point thereof lying inward from a relatively constricted mouth, the base of the tire being coincident with said mouth and the pressure being applied to said mouth, and withdrawing the vulcanized tire through said constricted mouth by compressing the wider portions of the body thereof, the withdrawal being effected successively from one end of the tire to the other, substantially as described.

3. The herein-described process of making rubber tires, which consists in subjecting the rubber to heat and pressure in a mold-cavity having the shape of the complete tire, the widest point thereof lying inward from a relatively constricted mouth, the pressure being applied at the mouth of the mold through an interspersed sheet or strip of canvas, and withdrawing the vulcanized tire along with the canvas through said con-

erected mouth by compressing the wider portions of the body thereof, substantially as described.

4. The herein-described process of making rubber tire, which consists in providing a mold having a plurality of mold-cavities, each having the shape of a complete tire and having its widest point lying inward from a relatively constricted mouth, subjecting the rubber to heat and pressure between said mold and a flat plate or plates, a sheet of canvas being interposed between the mold and plate, and the pressure being applied to the mouth of the mold-cavity, withdrawing the vulcanized tire through the constricted mouth of the mold-cavity by pulling on the canvas and thereby compressing the wider portions of the bodies of the tires to permit them to pass through said mouth, and then covering the canvas along the edges of the base of each tire, substantially as described.

701,843. MUD OR SAND BAND FOR VEHICLES. GEORGE D. HONAN and JOHN H. HONAN, Newton, Tex. Filed Oct. 22, 1901. Serial No. 70,686. (No model.)

Claim.—1. A device of the class described comprising a plate having a transverse slot, arm having a reduced and threaded end and portion passed upwardly through the slot and provided with a clamping-out at its upper end, a clamping-rod engaged with the arm adjacent to its lower end, and a second arm spaced from the first arm in the direction of projection of the screw.

2. A device of the class described comprising a plate having a transverse slot, arm having a reduced and threaded end and resilient shoulder, the threaded end being passed upwardly through the slot and having nut engaged with its upper end and to impinge the upper face of the plate, a clamping-rod engaged with the arm, and a second arm spaced from the first arm in the direction of projection of the screw.

3. A mud-band consisting of a plate provided with depending arms to lie against the side faces of an axle, and a clamping-rod engaged with one of the arms and arranged to impinge against the axle, the second arm being adjustable bodily toward and away from the first arm.

4. A mud-band comprising a plate having correlatively-adjustable depending arms adapted to lie at opposite sides of an axle, and a tie connecting the lower ends of the arms.

5. A mud-band comprising a plate having depending, correlatively-adjustable arms and means for holding them in fixed relation, and a tie formed integral with one arm and engaged adjustably with the other arm.

701,844. SPRING-HINGE. JOHN A. HOWLAND, Saginaw, Mich. Filed Mar. 2, 1906. Serial No. 50,448. (No model.)

Claim.—1. In a hinge of the character described, the combination of a keeper-plate adapted to be applied to a door-frame, a hinge, one of the leaves of which is adapted to be secured to a door, leaves pivotally connected to each other and provided with tongues for securing the other leaf of the hinge to the keeper-plate, and means for operating said leaves to project and retract said tongues, substantially as described.

2. In a hinge of the character described, the combination of a keeper-plate adapted to be secured to a door-frame and provided at one edge with slots guarded by ribs and adjacent to the opposite side edge with slots and bosses, a hinge, one leaf of which is adapted to be secured to a door, the other being provided with lugs to engage said slots and ribs, leaves upon the latter-named leaf pivotally connected to each other and provided with tongues to engage said slots and bosses, and a slidable operating device for actuating said leaves to project and retract said tongues, substantially as and for the purpose set forth.

701,845. HOG OR CATTLE SPLATTING MACHINE. JOHN C. HUNTER, South Omaha, Neb. Filed Feb. 7, 1906. Serial No. 50,678. (No model.)

Claim.—1. In a mechanism for dividing the carcasses of animals, the combination of standards or posts forming a main frame, each standard being grooved to permit of the reception and sliding therein of a quadrangular supplemental frame, means for bringing the carcass into proper position relative to the main frame, a knife pivoted at one end to the supplemental frame, and mechanism for retracting the supplemental knife-carrying frame to the top of the main frame when the cutting operation has been completed, substantially as set forth.

2. In a mechanism for dividing the carcasses of animals, the combination of a main frame, a supplemental frame movably mounted therein, the knife pivotally mounted on said frame, at one end and removably secured to the frame at the other end, and a handle mounted on said knife for assisting in operating said knife, substantially as set forth.

3. In a mechanism for dividing the carcasses of animals, the combination of a main frame, a supplemental frame vertically movable in said main frame, means for bringing the carcass into proper position relative to said main frame, cutting-mechanism mounted on the supplemental frame for dividing the carcass, and device mounted on the cutting mechanism for guiding the same relative to the carcass, during the operation of said cutting mechanism, substantially as set forth.

4. In a mechanism for dividing the carcasses of animals, the combination of a main frame, a supplemental frame vertically movable in said main frame, means for bringing the carcass into proper position relative to said frame, cutting mechanism mounted on the supplemental frame for dividing the carcass, device mounted in the cutting mechanism for guiding the same during the operation thereof, and supplemental cutting and breaking means mounted on the cutting mechanism for assisting in the operation of dividing the carcass, substantially as set forth.

5. A mechanism for dividing the carcasses of animals, comprising in its construction a main frame, a supplemental frame slidably mounted in said main frame, a knife pivotally secured at one end to said supplemental frame, means for removably mounting the free end of the knife in the supplemental frame, and means on said knife for guiding it during the operation of dividing the carcass, substantially as set forth.

6. A mechanism for dividing the carcasses of animals, comprising in its construction a main frame, a supplemental frame, means for permitting the supplemental frame to move vertically in said main frame, a knife mounted on said supplemental frame, and means on said knife for guiding the same, relative to the carcass of the animal, each means comprising a pin movably secured to the cutting edge of the knife, substantially as set forth.

7. A mechanism for dividing the carcasses of animals, comprising in its construction a main frame, a supplemental frame, means for permitting the supplemental frame to move vertically in said main frame, a knife mounted on said supplemental frame, and supplemental device on said knife for assisting in dividing the carcass, each device comprising a block adjustably mounted on the knife-blade, curved blades mounted on said block, relatively small arms extending upwardly from said block, and

rollers mounted on said arms, the entire mechanism being adapted to bear against the carcass, when the knife is moving downward and splitting the same, substantially as set forth.

8. In a mechanism for dividing the carcasses of animals, the combination of a main frame, means for bringing the carcass in proper position relative to said frame, a supplemental frame sliding in said main frame, and a knife pivotally mounted at one end in said supplemental frame and removably secured at its other end to said supplemental frame, substantially as set forth.

9. In a mechanism of the class described, the combination with suitable supporting means, and carcass-dividing means, of means carried by said dividing means for following the cavity occupied by the spinal cord of a carcass for directing said dividing means in its movement, substantially as described.

10. In a mechanism of the class described, the combination with suitable supporting means and a carcass-dividing knife carried thereby, of a pin carried by said knife and extending from the cutting edge thereof for following the cavity occupied by the spinal cord of a carcass for guiding said knife, substantially as described.

11. In a mechanism of the class described, the combination with a suitable support and a carcass-dividing knife carried thereby, of a pin pivoted to said knife and extending forwardly therefrom for following the cavity occupied by the spinal cord of a carcass for guiding said knife, substantially as described.

701,846. ANALYZING APPARATUS. GEORGE F. JENNINGS, New York, N. Y., assignor of one-half to Helen T. Shanks, New York, N. Y. Filed June 7, 1906. Serial No. 52,575. (No model.)

Claim.—1. In an analyzing apparatus, the combination of a rectangular tank, a series of pyramidal projections or partitions 5 mounted upon the bottom of said tank, a series of conical partitions 6 mounted at the edge of the tank whereby a series of conical mulling-chambers will be formed each having sloping walls, and a series of rollers rotatably mounted in each of said chambers whereby the rotation thereof will cause the material to progress successively through the several chambers and around the tank, substantially as and for the purpose set forth.

2. In an analyzing apparatus, the combination of a rectangular tank, a series of pyramidal projections or partitions 5 mounted upon the bottom of said tank, a series of conical partitions 6 mounted at the edge of the tank whereby a series of conical mulling-chambers will be formed each having sloping walls, a series of rollers rotatably mounted in each of said chambers whereby the rotation thereof will cause the material to progress successively through the several chambers and around the tank, and means for simultaneously rotating all of said rollers, substantially as and for the purpose set forth.

3. In an analyzing apparatus, the combination of a rectangular tank, a series of pyramidal projections or partitions 5 mounted upon the bottom of said tank, a series of conical partitions 6 mounted at the edge of the tank whereby a series of conical mulling-chambers will be formed each having sloping walls, a series of rollers rotatably mounted in each of said chambers whereby the rotation thereof will cause the material to progress successively through the several chambers and around the tank, and a removable grooved bottom for each of said mulling-chambers and with which said rollers cooperate, substantially as and for the purpose set forth.

701,847. HYDROCARBON-BURNER. CHARLES J. JENNINGS, St. Louis, Mo. Filed June 14, 1906. Serial No. 54,026. (No model.)

Claim.—In a hydrocarbon-burner, the combination of a supply-pipe provided with a closed end, but with perforations on the side thereof, an

adjustable jacket engaging and including said pipe and extending beyond said perforations, but leaving a clearance-space between it and the said supply-pipe, and a deflector placed above said jacket and on the end of said pipe, said deflector being of greater diameter than in the interior of said supply-pipe substantially as described.

701,848. CONSTRUCTION OF COULERS OR TRACKS FOR UTILITY. CHARLES H. JONES, West Grove, England. Filed Aug. 26, 1901. Serial No. 72,901. (No model.)

Claim.—1. In a bicycle-track, the combination with a series of inclined bottoms each having one end resting on the floor or ground, of curved horizontally-disposed cross-pieces secured to said bottoms, and forming therewith an endless track, levers extending outwardly from the upper portions of said bottoms, and having their lower ends engaging the floor or ground, and means for preventing the lower ends of said bottoms from slipping outwardly, substantially as described.

2. In a bicycle-track, the combination with a series of inclined bottoms, each having one end resting on the floor or ground, of curved horizontally-disposed cross-pieces secured thereto and forming therewith an endless track, curbs of said bottoms being separated to permit of spectators seating between them, levers secured to the upper of said cross-pieces and engaging the ground or floor, devices engaging the lower ends of said bottoms, to prevent them from moving outwardly, and flexible connections secured to the said upper cross-bar and to the floor for exerting a downward pressure upon said cross-bar and steadying the track, substantially as described.

3. In a bicycle-track, the combination with a series of inclined bottoms, each having one end resting on the ground or floor, of curved horizontally-disposed cross-pieces secured to said bottoms, and forming therewith an endless track, levers connected with the upper of said cross-bars, check-blocks, to receive the lower ends of said bottoms and prevent them from slipping, retaining devices for securing said blocks to the floor or ground, a series of eyes secured to one of said cross-bars and to the floor or ground, and a flexible connection passing through said eyes, a portion of said bottoms being separated to allow spectators to see between them, substantially as described.

4. A bicycle-track comprising among its members, a series of substantially parallel bottoms disposed at an angle with the floor or support for the track arranged in substantially circular form, and having their lower ends engaging the floor, or support, certain of said bottoms being held at short distances from each other, to permit the riders to be seen through the spaces between them, substantially as described.

701,849. MOSQUITO-BAR OR CANOPY SUPPORT. FREDERICK JONES, New Orleans, La. Filed Feb. 24, 1906. Serial No. 55,260. (No model.)

Claim.—1. The combination with the head-posts of a bedstead, of a mosquito-bar or canopy support comprising a horizontally-disposed main frame connected in its head-posts and having side bars and front and rear cross-bars, brackets interposed between the head-posts and the side bars of the main frame, side-bars disposed below and in planes within those of the side bars of the main frame, hangers connecting said side-bars to the front and rear cross-bars of the main frame, and a bar D held to and slidable fore and aft on the side-bars, and adapted for the connection of a mosquito-bar or canopy.

2. The combination with the head-posts of a bedstead having threaded sockets in their upper ends, and also having removable tape with threaded shanks disposed in said sockets, of a mosquito-bar or canopy support comprising a horizontally-disposed main frame having side bars provided with eyes receiving the shanks of the removable post-tape, and also having front and rear cross-bars, side-bars disposed below and in planes within those of the side bars of the main frame, hangers connecting said side-

bars to the front and rear cross-bars of the main frame, a bar D held to and slidable fore and aft on the side-bars, and adapted for the connection of a mosquito-bar or canopy, and brackets having eyes at their upper ends receiving the chains of the post-top and interspersed between the eyes of the main frame and the ends of the posts, and also having curving linear portions at their lower ends bearing against the forward sides of the posts, and forwardly-reaching arms connected to the side bars of the main frame.

701,850. DEVICE FOR SUPPORTING SHOES WHILE POLISHING SAME. CHARLES G. KELLER, St. Louis, Mo. Filed Aug. 28, 1901. Serial No. 72,045. (No model.)

Claim.—1. A device of the class described, comprising a support, a double last adjustably mounted upon the support, a bar pivotally carried upon the support, and means for retaining its lower end in the shoe, and means for retaining the entire device to a rigid object, substantially as specified.

2. A device of the class described, comprising a last of two shoes suspended to a rod or support, a bar pivotally carried by the rod, a heelpiece provided at the lower end of the bar, a means for retaining the shoe upon the last in a rigid position, and means whereby the entire device is supported to a rigid object, substantially as specified.

3. A device of the class described, comprising a rod adjustably carried by a bracket, a double foot-last carried by said rod, a slot formed in said last whereby the same may be secured and adjusted upon the rod, a bar pivotally carried by said rod, a heelpiece secured to the lower end of the bar, and a pawl carried by the rod, and meshing with ratchet-teeth formed on the bar, for regulating the tension to the shoe rigidly holding it upon the last, substantially as specified.

701,851. GARMENT-SUPPORTER. VALENTIN KELLER, Milwaukee, Wis. Filed Mar. 20, 1901. Serial No. 100,505. (No model.)

Claim.—1. A garment-supporter consisting of two pivotally-carried sheet-metal sections, the inner one of which is bent to have upwardly-

diverging sides and provided with outwardly-projecting upwardly-inclined bars, the outer section being of π form and having its sides in opposition to those of said inner section when in normal position.

2. A garment-supporter consisting of two pivotally-carried sheet-metal sections, the inner one of which is bent to have upwardly-diverging sides provided with outwardly-projecting upwardly-inclined bars and upper ears, the outer section being of π form and provided with a recess in its bend for engagement of said ears when in normal position.

701,852. PROCESS OF MAKING DRESSING-FLUENTS. WILLIAM T. KENNEDY, Montgomery, Ala., and WILLIAM T. KENNEDY, administrator of George W. DIXON, deceased. Filed Mar. 12, 1902. Serial No. 93,092. (No specimens.)

Claim.—The process of compounding a liquid chemical composition for the purpose stated, comprising essentially chlorid of lime, carbonate of soda, boracic acid, permanganate of potash, in substantially the proportions specified, consisting in incorporating chlorid of lime and water, then permitting precipitation and decanting the supernatant fluid; then dissolving carbonate of soda in water by means of heat, then mixing the solutions of chlorid of lime and carbonate of soda and permitting the combined solution to stand until precipitation is complete; then removing the supernatant solution; and then incorporating boracic acid and permanganate of potash and permitting substantially complete precipitation, and then removing the supernatant fluid from the residuum, substantially as set forth.

701,853. WIND-REGISTERING ATTACHMENT FOR VEHICLES. GEORGE A. KENNEDY, Marshall, Mich. Filed Aug. 20, 1901. Serial No. 72,722. (No model.)

Claim.—In a speed-registering mechanism, the combination with a governor consisting of a stem having a tapered and a sliding collar thereon, spring-arms connected at their opposite ends to the collar; of a pivoted lever with a toothed sector mounted on the sliding collar, a suitably-connected piston meshing with the sector, means for rotating the stem to give the springs an inward and outward movement and move the sliding collar upward or downward as to oscillate the pivoted lever, and a tension-spring connected to said oscillating lever, and adjusting means on the same whereby to increase or decrease the resistance of the oscillating lever to its action by the governor and enable the gearing to be set with accuracy, said tension-spring also serving to coast with the spring-arms to absorb vibration, thereby preventing the said oscillating lever from being unduly influenced by the jolting of the vehicle to which said registering mechanism is attached, substantially as specified.

701,854. SWING. GEORGE S. KERR, Horton, Pa. Filed Mar. 12, 1901. Serial No. 50,820. (No model.)

Claim.—1. A bridge for a swing comprising a horizontal supporting-bar, clamping-bars movably attached to the upper side of the opposite end portions of said supporting-bar, hinges adjustably attached to the opposite end portions of the supporting-bar and the lower outer ends of

the clamping-bars, and clamping-balls extending through the supporting-bar and the free terminals of the clamping-bars.

2. A bridge for a swing comprising a horizontal supporting-bar, movable clamping-bars connected to said supporting-bar adjacent to opposite extremities thereof, both bars being wholly located above the upper side of said supporting-bar, clamping means engaging the latter bar and the free extremities of the clamping-bars, hinges for connecting the clamping-bars, each having the heel thereof resting on the supporting-bar formed with a slot, said supporting-bar also having slots to coincide with those of the hinge-leaves, and means for connecting the said slotted hinge-leaves to the bar.

3. A supporting means for a swing comprising a horizontally-disposed plate with a lower depending socket portion at the center thereof having a rectangular slot opening out from the bottom and an upper enlarged recess of square form to provide horizontal shoulders adjacent to the long sides of the rectangular slot, the said shoulders having at their centers and at diametrically opposite points in planes at right angles to the slot in the bottom of the socket transverse cuts, in the form of recesses, and a vertically-depending shank for attachment to a swing-supporting means and having an upper head of a transverse extent less than the width of the said rectangular slot and provided with laterally-projecting transverse ends of equal length in alignment with each other and having a combined extent from the shank slightly less than the transverse extent of the said upper square recess and less than the length of the said slot, the shank being rotatable in the slot and the transverse in the square recess for the purpose of detaching and seating the said transverse.

4. A bridge for a swing comprising a supporting-bar, clamping-bars hinged thereto, and clamping-balls extending through the supporting-bar and the free terminals of the clamping-bars.

5. A bridge for a swing comprising a supporting-bar, clamping-bars movably connected to the same, stop-blocks on the supporting-bar, and clamping-balls extending through the supporting-bar and the free terminals of the clamping-bars.

701,855. WATER-WHEEL. JAMES E. KIM, Rochester, N.Y. Filed Sept. 18, 1891. Serial No. 21,302. (No model.)

Claim.—1. A water-wheel comprising speed heads, wings between the heads and joined at their edges thereto, and peripheral plates joined at their edges to the heads and having their proximal ends passing by each other and spaced apart, the inner end of each plate being attached to a wing a short distance from its extremity and having the projecting portion bent inward, and the outer end of each plate being bent outward, the overlapped end portions of adjacent plates being outwardly convergent, substantially as specified.

2. A water-wheel comprising speed heads, long and short wings alternately arranged between the heads and joined at their edges thereto, the long wings extending to the axis of the wheel and the short wings having their inner ends spaced from said axis, and peripheral plates joined near their inner ends to the outer extremities of the respective wings and reaching toward their outer ends from the axis of the wheel and having the outer end portions of each inwardly bent, spaced from and passing by the inner end portions of the proximal plates, and having the inner end of each plate inwardly bent, the adjacent bent portions being outwardly convergent, substantially as set forth.

3. A water-wheel comprising speed heads having their outer portions convergent, long wings extended from the center of the wheel outward, short wings radially disposed and subdividing the spaces between the long wings and having their inner ends spaced from the axis of the wheel and sharpened, and peripheral plates joined at their edges to the heads and having their proximal ends passing by each other and spaced apart, said plates gradually reaching from the axis of the wheel toward their outer ends, and having the outer end portions bent inward and the inner end of each plate being attached to the outer end of a wing and inwardly bent, the proximal bent ends of adjacent wings being outwardly convergent, substantially as specified.

701,856. VEHICLE-AXLE. JAMES E. KIM, Rochester, N.Y. Filed Apr. 18, 1892. Serial No. 100,884. (No model.)

Claim.—The combination with an axle having a straight squared portion inside of the shaft, a tapered squared shoulder extending outwardly from said straight portion, a long tapered squared portion extending outwardly from said shoulder, a second tapered squared shoulder extending outwardly from said long portion, and a curve-threaded end; of a chain having an interior opening squared to fit said axle, and removably mounted upon said axle; a thimble adapted to be mounted upon said chain and having ribs to hold the thimble in the hub against rotation; and a nut curve-threaded upon said curve-threaded portion of the axle to hold the chain and thimble in position, substantially as specified.

701,857. PYROXYLIN COMPOUND. JAMES E. KIM, Philadelphia, Pa. Filed Feb. 5, 1892. Serial No. 21,307. (No specimens.)

Claim.—1. The process which consists in adding to an amorphous cellulose compound, either, and curing or vulcanizing the same with the aid of heat.

2. The process of curing or vulcanizing an amorphous cellulose compound which consists in adding to said cellulose compound either in its divided state, and subjecting the same to a high temperature.

3. The process of producing an article useful as an electric insulator which consists in adding to an amorphous cellulose treated with a solvent, either in its divided state, and subjecting the same in the action of heat.

4. The process of curing or vulcanizing amorphous cellulose which consists in subjecting the cellulose to a solvent, adding either to the compound, intermixing said cellulose with said cellulose, and subjecting the compound to the action of heat.

5. An article of manufacture a compound consisting of amorphous cellulose and either cured or vulcanized with the aid of heat.

701,858. SLOT-MACHINE. WILLIAM KLEINBERG, Ploos, Austria-Hungary. Filed Mar. 31, 1902. Serial No. 100,720. (No model.)

Claim.—1. In a slot-machine for vending pasteboard tickets, with delivery-slide arrangement, the combination of a number of flat springs, secured with the upper ends to the front face of the machine and projecting with the lower free ends into the delivery-path, a curved flat spring, secured with the curved end to the bottom plate of the machine and projecting with the free forward end through an aperture in the bottom plate of the machine and into the delivery-path, a shield or housing covering the said flat-springed springs, and a housing for the curved spring, the parts being constructed, arranged and working, substantially as and for the purpose set forth.

2. In a slot-machine for vending pasteboard tickets, with delivery-slide arrangement, the combination of a number of flat springs, secured with their upper ends to the front face of the machine and projecting with the lower free ends into the delivery-path, a plurality of curved flat springs, secured with the curved end to the bottom plate of the machine and projecting with the free forward ends through an aperture in the bottom plate of the machine and into the delivery-path, a shield or housing covering the said flat-springed springs, and a housing for the curved springs, all substantially as and for the purpose specified.

701,859. AIR-SHIP. CARL F. A. KLOSS, Indianapolis, Ind. Filed July 8, 1901. Serial No. 57,490. (No model.)

Claim.—1. In an air-ship, the combination with a gas-reservoir, of a pilot-house suspended from the bottom thereof, a motor arranged in said pilot-house, propellers connected to said motor for elevating and driving the ship, booms pivotally connected to the bottom of the gas-reservoir, flexible wings connected along one of their edges to the bottom of the gas-reservoir and along another edge to the booms, said wings being adapted when spread to prevent rolling of the ship, means for opening said wings, and means for closing the same.

2. In an air-ship, the combination with a gas-reservoir, of a pilot-house suspended from the bottom thereof, a motor arranged in said pilot-house, transversely-extending shafts connected to said motor and passing through the pilot-house, rotatable tubes including said shafts, propellers mounted upon said tubes and operatively related to said shafts, a tail-shaft extending rearwardly from said pilot-house and also connected to said motor, a tube including said tail-shaft, a steering-propeller adjustably mounted upon said tube and adapted to swing in a horizontal plane, gearing between said shaft and said propeller, adjustable bearings arranged in said tube and in which the tail-shaft is journaled, a rod extending through said shaft-tube, and rotatably mounted therein, and cone carried by said rod and engaging said bearings for adjusting the latter, whereby the gearing between the tail-shaft and the steering-propeller may be caused to reverse the direction of movement of the steering-propeller.

3. In an air-ship, the combination with a gas-reservoir, of a pilot-house suspended from the bottom thereof, a motor arranged in said pilot-house, transversely-extending shafts connected to said motor and passing through the pilot-house, rotatable tubes including said shafts, propellers mounted upon said tubes and operatively related to said shafts, a tail-shaft extending rearwardly from said pilot-house and also connected to said motor, a tube including said tail-shaft, a steering-propeller adjustably mounted upon said tube and adapted to swing in a horizontal plane, gearing between said shaft and said propeller, adjustable bearings arranged in said tube and in which the tail-shaft is journaled, a rod extending through said shaft-tube and rotatably mounted therein, cone carried by said rod and engaging said bearings for adjusting the latter, whereby the gearing between the tail-shaft and the steering-propeller may be caused to reverse the direction of movement of the steering-propeller to the desired position.

701,860. PAPER-BOX MACHINE. ALBERT KOENIG, St. Louis, Mo. Filed Sept. 14, 1901. Serial No. 70,641. (No model.)

Claim.—1. In a machine for making paper boxes, a table; a form-support mounted upon the table; a "former-block" pivotally mounted in position to engage the form-support, the ends of said block being recessed

to receive the ends of the form as they are folded around the block; and means for operating the "former-block" substantially as specified.

2. In a machine for making paper boxes, a table; bearing-blocks mounted upon the table; a gage adjustably mounted upon the table between the bearing-blocks; a form-support movably mounted upon the table in front of the gage, the upper surface of said form-support being corrugated and inclined backwardly; a shaft mounted in the bearing-blocks; an arm pivotally mounted upon the shaft; a former-block adjustably attached to the front end of said arm; a foot-lever under the table; and a connection between the foot-lever and the said arm to operate the former-block, substantially as specified.

3. In a machine for making paper boxes, a table; bearing-blocks mounted upon the table; an adjustable gage mounted upon the table between the bearing-blocks; a former-block pivotally mounted in said bearing-blocks in position to engage the form-support, the ends of said block being recessed to receive the ends of the form as they are folded around the block; a form-support mounted upon the table in front of the gage, and in position to be engaged by the former-block, the upper surface of said form-support being corrugated and inclined backwardly; a foot-lever mounted under the table; and a connection between the foot-lever and the former-block for operating the former-block, substantially as specified.

701,861. COMBINED FEEDER AND BRAKE. HENRIK ERIKSSON, St. Louis, Mo. Assignor to Charles C. Green, St. Louis, Mo. Filed Feb. 24, 1902. Serial No. 58,674. (No model.)

Claim.—1. In a device of the class described, a feeder-scoop; brake-blocks attached to the ends of the feeder-scoop; forks pivotally attached to the brake-blocks, and embracing the car-axle; hangers extending downwardly from the car-bed and having cam-plates in their lower ends; pins rigidly fixed in said forks and operating in said cam-plates as required to move the brake-blocks away from the car-wheel when the feeder is elevated, and upon the brake-blocks to the car-wheel when the feeder is lowered; and means of raising and lowering the feeder, substantially as specified.

2. In a device of the class described a feeder-scoop; brake-blocks attached to the ends of the feeder-scoop; forks pivotally connected to the brake-blocks and embracing the car-axle; hangers extending downwardly from the car-bed, and having cam-plates in their lower ends; pins rigidly fixed in said forks and operating in said cam-plates; an operating-rod extending upwardly from the frame of the feeder; a hook at the upper end of said operating-rod; a slide mounted in position to be operated by the hook impact of the controller, and in position to engage said hook, so that when the controller is operated to shut off the current, the slide will be moved to release the hook and thereby the feeder, and set the brake, substantially as specified.

3. In a device of the class described, brake-blocks framed together; forks pivotally connected to the brake-blocks, and embracing the car-axle;

701,862. INSECT-EXTERMINATOR. MAX KURTZ, Berlin, Mo. Filed Mar. 4, 1902. Serial No. 57,941. (No model.)

Claim.—1. An insect-exterminator comprising a frame having angularly-disposed walls, a lamp located in the angle formed between the walls, a pan arranged below the lamp and in the angular space formed between the walls of the frame and adapted to contain an insecticide, and interlocking means between the adjacent sides of the pan and frame, substantially as set forth.

2. In an insect-exterminator, a frame comprising angularly-disposed side walls, a top for closing the space formed between said walls, a lamp suspended from the top between the side walls, supports near the lower ends of the side walls, and a pan having its sides fitted against the inner faces of the side walls and provided with off-standing hook-shaped lips to engage with the aforementioned supports and hold the pan in suspension beneath the lamp, substantially as set forth.

3. In an insect-exterminator, a folding frame comprising angularly-disposed walls hingedly connected at one edge, a top hinged to the upper end of one of the side walls and adapted to make detachable connection at the opposite edge with the other end of the other side wall, a lamp to be suspended from said top, and a pan located beneath the lamp and detachably connected with the sides of the frame, substantially as set forth.

4. The herein-described insect-exterminator comprising side walls hinged at their rear vertical edges, a top hinged to the upper end of one of the sides and provided at its opposite edge with fastenings to make detachable connection with the upper end of the other side, rings near the front edges of the sides, supports near the lower ends of the sides, a lamp suspended from the top between the side walls, a reflector located in the angle formed between the said sides, a pan having its sides angularly disposed and adapted to come close against the sides of the frame, and hook-shaped lips projected from the sides of the pan to make interlocking connection with the aforementioned supports for holding the pan in suspension, substantially as specified.

701,868. PROCESS OF MAKING ELECTRIC BRUSHES. RICHARD A. LAURENCE, New Haven, Conn. Assignor to National Carbon Company, Cleveland, Ohio, a Corporation of New Jersey. Filed Dec. 26, 1901. Serial No. 57,974. (No model.)

Claim.—The herein-described process of making electric brushes which consists in winding wire spirally and longitudinally upon plates of green carbon, in placing one or more of these plates, so wound, between other green-carbon plates not so wound, in compressing this composite plate so as to make the surface of the several plates into a homogeneous mass, and in finally taking the resultant structure.

701,864. LUBRICATING DEVICE. ANDREW LUDWIG, Elkhart, Ind. Filed Dec. 30, 1901. Serial No. 57,723. (No model.)

Claim.—The combination with a journal and journal-box, of a base-piece G, having a perforated and recessed upper face curved in cross-section to match the under convex surface of the journal; a perforated sheepskin covering L cut out at the corners to form projecting portions at the sides and ends which portions depend below the sides and ends of the base-piece into the bottom of the journal-box; and a spring secured to the lower surface of the base-piece and bearing against the bottom of the journal-box for pressing the sheepskin and base-piece upwardly against the journal.

701,865. BRIQUET AND METHOD OR PROCESS OF PRODUCING SAME. EDWARD S. BRADY, Philadelphia, Pa. Filed July 26, 1901. Serial No. 58,787. (No model.)

Claim.—1. The process of weatherproofing and strengthening briquets composed of coal, coke, or the like, and molasses as a binding agent, which consists in subjecting said briquets to sufficient heat to coke the molasses, substantially as set forth.

2. The process of weatherproofing and strengthening briquets composed of coal, coke, or the like, in which molasses is the binding agent, which consists in subjecting such briquets, for a very brief period (about a minute) to a temperature considerably above that necessary to coke the molasses, whereby said molasses is quickly coked, substantially as set forth.

3. A briquet composed of coal, coke, or the like, and molasses as a binding agent, in which the molasses has, after incorporation into said briquet, been coked, whereby the briquet is rendered weatherproof and strengthened, substantially as set forth.

701,866. BUTCHER'S SAW. GEORGE MEYER, Indianapolis, Ind. Assignor to E. C. Atkins & Company, Indianapolis, Ind., a Corporation of Indiana. Filed July 1, 1901. Serial No. 58,791. (No model.)

Claim.—1. The combination, in a butcher's saw, of a frame the heel whereof is tilted and extends rearwardly from the point of union with the saw-blade, said saw-blade, and suitable device for fastening and tightening said saw-blade mounted upon the rearwardly-extending heel of the frame below the handle and out of ordinary danger of contact with the meat, said fastening device being provided with wings covering the slit in the frame-heel, substantially as set forth.

2. The combination, in a butcher's saw, with a saw-blade, of a frame in which said blade is mounted having a rearwardly-extending heel provided with a vertical slit for receiving the end of the saw-blade and a horizontal slit for receiving the tightening-bolt, and said tightening-bolt, substantially as set forth.

3. The combination, in a butcher's saw, of the saw-blade, the frame having a rearwardly-extending heel in which are vertical and transverse slits for receiving the saw-blade and the tightening-bolt respectively, said tightening-bolt, a wing-out on the outer end thereof, and a bearing-block interposed between said wing-out and the extreme end of the frame-heel, substantially as set forth.

4. The combination, in a butcher's saw, of the saw-blade, the frame having a rearwardly-extending heel in which are vertical and transverse slits for receiving the saw-blade and the tightening-bolt respectively, said tightening-bolt connected to said saw-blade and provided with wings extending forwardly along the frame-heel and covering the other-wise open portion of the slit therein in that point, substantially as set forth.

701,867. THILL-COUPING. ROBERT HILL, Old Orchard, and CHARLES H. BLANCHARD, St. Louis, Mo. Filed Dec. 12, 1901. Serial No. 55,615. (No model.)

Claim.—A thill-coupling, consisting of a clamp composed of two members, a recess formed in the under side of the upper member, the lower member adapted to fit within said recess, the inner upper corner of the lower member rounded for the purpose of allowing the said member to be placed in locking position over a bushing, and means for preventing the upper member from becoming detached from the vehicle when in an upwardly-inclined position should the lower member become loose, substantially as specified.

701,868. LEBOVITS-GALLEY. FREDERICK R. HEDGECOCK, Brooklyn, N. Y. Filed May 20, 1901. Serial No. 51,051. (No model.)

Claim.—1. A galley having a bottom, and side and end members, and all rigidly secured together, said end members being provided with pins, and a removable side member provided with apertures for engaging the said pins.

2. A galley provided with an undercut groove, a slidable jaw provided with a dovetailed portion engaging said groove and also provided with a lug, and a lever mounted upon said lug and provided with a cam for engaging a stationary part of the galley, for the purpose of securing said slidable jaw thereto.

3. A galley, comprising a side member provided with an undercut groove, an L-shaped slidable member provided with a dovetailed portion engaging said groove and also provided with a lug, and a lever pivoted upon said lug and provided with cam for engaging a fixed portion of said galley.

4. A galley, comprising a side member provided with an undercut groove, an L-shaped slidable member provided with a dovetailed portion engaging said groove and also provided with a lug, a lever pivoted upon said lug and provided with cam for engaging a fixed portion of said galley, and members engaging said side member and provided with pins, and a side member provided with holes for engaging said pins.

5. A galley, comprising a side member provided with an undercut groove, an L-shaped slidable member provided with a dovetailed portion engaging said groove, and also provided with a lug, a lever pivoted upon said lug and provided with cam for engaging a fixed portion of said galley, and members rigidly secured to said side member, and a side member removably secured to said end members.

701,869. CARBON BRUSH AND PROCESS OF MAKING SAME. WILLIAM HENRI, Jersey City, N. J., assignor to Eastern Carbon Works, Jersey City, N. J., a Corporation of New Jersey. Filed Nov. 5, 1901. Serial No. 51,944. (No model.)

Claim.—1. The process of making electric brushes, consisting of placing in a mold alternate layers of relatively high and low resistance

and submitting them to a pressure capable of causing them to firmly adhere.

2. The process of making an electric brush, consisting of making a resistance composition by mixing a substance similar to ground stone, mica, clay, &c., with carbon, and putting a layer of this material and a layer of relatively high conductivity in a mold and subjecting the same to pressure.

3. The process of making a carbon brush, consisting of making a high-resistance composition of material similar to ground stone, mica, &c., and carbon, and a suitable plastic binder; and alternating this composition and carbon in layers; and in subjecting the whole to a high pressure.

4. A carbon brush composed of a layer of carbon and a layer of a mixture of carbon and non-conductor.

5. A carbon brush composed of a layer of high-conductivity material and a layer of relatively low conductivity material, which latter comprises a mixture of carbon and a substance similar to ground stone, mica, clay, &c.

6. A carbon brush consisting of alternate layers of varied resistance, the high-resistance layers being of carbon and the low resistance of a mixture of carbon and material similar to ground stone, mica, &c.

7. A carbon brush consisting of layers of different resistance pressed into intimate contact with each other.

701,870. ICE-CREAM PRESSER. HENRY MORRIS, JR., Philadelphia, Pa. Filed Aug. 20, 1902. Serial No. 124,827. (No model.)

Claim.—1. In an apparatus of the character described, the combination with a driving-shaft and two sets of gears thereon, of two counter-shafts having loosely mounted thereon sets of gears meshing with the respective sets on the driving-shaft, a clutch mechanism on each of said counter-shafts intermediate the loose gears and adapted to render the adjacent gears active or inactive as desired, and mechanism whereby the said counter-shafts may be operatively connected with the driving-shaft and one of the driving shafts, substantially as described.

2. The combination with the cam and piston-rod of a freezing vessel, of a frame adjacent thereto, a vertically-disposed bushing on said frame, two oppositely-disposed beveled wheels on the upper and lower end of said bushing, a driving-shaft provided with a gear engaging said wheels, a cap having a sliding connection with the upper wheel, a sleeve having a similar connection with the lower wheel, a central shaft in said bushing offset at its upper end to said cap, a sliding connection between said cap and sleeve, and means for operating said connection, together with interlocking portions for the sliding ends of the piston-rod and the said central shaft, and interlocking portions for the sleeve and the cap, substantially as described.

701,871. HAND-CLIPPER. JAMES A. HOLLAND, Baltimore, Md. Filed Oct. 5, 1901. Serial No. 77,901. (No model.)

Claim.—1. In a hand-clipper, the combination of a pair of jaws, one having a pair of blades with an intervening space between them and the other a single blade partially movable into the space between said pair of blades, means for holding the jaws in open position, and a spring for closing said jaws.

2. In a hand-clipper, the combination of a pair of jaws, one jaw having a pair of blades and the other a single blade partially movable between said pair of blades, and a spring connected to the jaws for closing one of the latter inwardly toward the other.

3. In a hand-clipper, the combination of a pair of jaws having an

intervening space between them and the other jaw a single blade partially movable between said pair of blades, angle-plates secured to the upper central portions of the blades, a spring attached to said angle-plates, and a catch-bar pivoted to one jaw and adapted to removably engage the other jaw.

4. In a hand-clipper, the combination of a pair of jaws pivotally connected, one jaw having a pair of blades arranged parallel and spaced apart and the other jaw having a single blade movable between said pair of blades, angle-plates secured to the jaws, a spring attached to said plates, a handle depending from one of the plates, and means for holding the jaws open.

5. A hand-clipper comprising a pair of pivotally-connected jaws, each of said jaws being provided with a cutting-blade, means for holding said jaws in open fixed position, and a spring for closing said jaws when released.

6. A hand-clipper comprising a pair of pivotally-connected jaws, each of said jaws being provided with a cutting-blade, a brace pivoted to one of said jaws and adapted to engage the other and hold it in open position, and means for closing said jaws upon the disengagement of the brace being effected.

7. A hand-clipper comprising a pair of pivotally-connected jaws, each of said jaws having a cutting-blade, a brace or catch bar pivoted to one of said jaws and adapted to removably engage the other jaw, and a spring for closing said jaws.

701,872. SWINGING-MACHINE. FRANK J. McDERMOTT, New Bedford, Mass. Filed July 20, 1901. Serial No. 70,941. (No model.)

Claim.—1. In a swinging-machine, a suspended chain of gearing, a carriage, cable connections between the carriage and the gearing, a crank-shaft operated by the gearing, and connections between said shaft and the cables, substantially as specified.

2. In a swinging-machine, a suspended chain of gearing, a carriage, cable connections between the carriage and gearing, a crank-shaft, rock-levers on opposite sides of the casing, connections between said rock-levers and cranks on the crank-shaft, and guides carried by the rock-levers and through which the cables pass, substantially as specified.

3. In a swinging-machine, a casing designed to be secured to an overhead support, a main shaft in the casing, drums mounted on the outer ends of said shaft, cords or cables engaging the said drums, a carriage supported by the cords or cables, a winding-drum on the shaft, means for rotating the winding-drum and shaft, a gear-wheel loosely mounted on the shaft, means for locking said gear-wheel in connection with the shaft, a

crank-shaft, a train of gearing between said crank-shaft and said gear-wheel, rock-levers on opposite sides of the casing, connections between said rock-levers and cranks on the crank-shaft, and guides carried by the rock-levers and through which the cords or cables pass, substantially as specified.

4. In a swinging-machine, a casing adapted to be secured to an overhead support, a main shaft arranged in the casing, a winding-drum on said shaft within the casing, a cord or cable extended from said drum through an opening in the bottom of the casing, a ratchet-wheel mounted on said shaft, a gear-wheel loosely mounted on the shaft, a spring-pressed pawl carried by the gear-wheel for engaging with the ratchet-wheel, drums on the outer ends of said shaft, a carriage having cord or cable connections with said drums, a crank-shaft having double cranks at its opposite ends, a chain of gearing between said crank-shaft and said gear-wheel, rock-levers on opposite sides of the casing, the said rock-levers being secured at their centers, flat-rods extended from the crank members respectively to the upper and lower portions of the levers, and guides on the levers through which the carriage-suspending cords or cables pass, substantially as specified.

701,873. WATER-FILTER. JAMES W. McLEAN, Joplin, Mo. Filed Mar. 1, 1902. Serial No. 55,322. (No model.)

Claim.—1. A water-filter comprising an outer cylinder provided with means for attaching it to a service pipe or bibb and having a discharge for unfiltered water extending through its side, and a rotatable filtering body or cylinder carrying a suitable valve or cut-off whereby the opening in the discharge is opened or closed by the rotation or turning of said filtering body or cylinder, substantially as and for the purpose set forth.

2. A water-filter, comprising an outer cylinder provided with means for connecting it with the service pipe or bibb, and having at its upper and lower ends respectively suitable notched ends and a discharge for unfiltered water, and a rotatable filtering body or cylinder having discharge-ports for the filtered water adapted to engage the notched ends, and a valve or cut-off carried by said filtering body or cylinder to open or close the unfiltered-water discharge, substantially as and for the purpose specified.

701,874. ILLUSTRATING APPARATUS. FREDERICK R. HEDGECOCK, Springfield, Mass. Filed Jan. 17, 1902. Serial No. 72,411. (No model.)

Claim.—1. The combination, in an illustrating apparatus, of a display-board having a diagram delineated thereon and openings therein at determined points, reflectors having transparent closures, secured back of said openings, pictures permanently affixed to certain of said closures, and electric lamps in said reflectors, with a keyboard equipped with switches F and G and a plurality of switch-plugs arranged at determined points corresponding to the locations of certain of said lamps, and electric circuits connecting the lamps, switches and switch-plugs with a source of electrical supply, substantially as shown and described.

2. The combination, in an illustrating apparatus, of a display-board having a diagram delineated thereon and openings therein at determined points, sliding reflectors having transparent closures, secured back of said openings, pictures permanently affixed to certain of said closures, and electric lamps inside and attached to the rear of said reflectors, with a keyboard equipped with switches F and G and a plurality of switch-plugs arranged at determined points corresponding to the locations of certain of said lamps, and electric circuits connecting the lamps, switches and switch-plugs with a source of electrical supply, substantially as shown and described.

3. The combination, in an illustrating apparatus, of a display-board having a diagram delineated thereon and provided with openings at determined points and other openings arranged in independent series, practically adjacent to each other, reflectors having transparent closures, secured back of said openings, pictures permanently affixed to the closures at said first mentioned openings, and electric lamps in said reflectors, with a keyboard equipped with switches F and G and a plurality of switch-

4. In an illustrating apparatus, a display board or screen having a diagram delineated thereon, openings in said screen at determined points, other openings arranged in independent series, approximately adjacent to each other, reflectors disposed in said openings, transparent closures for said reflectors, incandescent lamps within the reflectors, electric circuits to said lamps, switches F and G and non-reversible switch-plugs in the circuits, incandescent lamps secured to and projecting from the face of the screen, an electric circuit to each of said last-mentioned lamps, and spring-actuated switch-plugs in each lamp-circuit last mentioned, to close said circuits as required and to automatically break the circuits when pressure is removed from the plugs, substantially as specified.

701,875. WIRE STRAIGHTENING AND CUTTING MACHINE. ALAN E. SHAW and HARVEY SHAW, Bridgeport, Conn., assignors to the A. E. Shaw Machine Company, Bridgeport, Conn., a Corporation of Connecticut. Filed July 17, 1901. Serial No. 68,648. (No model.)

Claim.—1. In a machine of the character described, the combination with independently-operated feeding and cutter-operating mechanisms, a cutter, and horizontally-movable guide-plates, of a stop, a clutch, and a connection between the stop and the clutch, the parts being so combined and arranged that when the stop is engaged by the wire connection will be made with the cutter-operating mechanism, a blank will be covered and released, and the guide-plates and cutter will be returned to their normal position and the cutter-operating mechanism disconnected.

2. The combination with guide-plates having grooves in their contiguous edges which together form a receiving-socket, of means for opening and closing the guide-plates so that blanks may drop out.

3. The combination with guide-plates having grooves in their contiguous edges and oblique slots 45, of slots 44 which pass through the slots and a lever engaging the guide-plates and acting in connection with the slots and slots to open and close the guide-plates.

4. The combination with guide-plates having grooves in their contiguous edges which together form a receiving-socket, of a stop for the wire adapted to fit within the socket, a cutter and means for opening the guide-plates to permit covered blanks to drop out.

5. The combination with guide-plates having grooves in their contiguous edges which together form a receiving-socket, of an adjustable stop for determining the length of blanks, means for loosely connecting said stop to one of the guide-plates, a cutter and means for opening and closing the guide-plates.

6. The combination with guide-plates having grooves in their contiguous edges which together form a receiving-socket, of an adjustable stop carried by one of the guide-plates, a cutter, means for opening and closing the guide-plates and means for releasing the blanks drop when the guide-plates are opened.

7. The combination with guide-plates having grooves in their contiguous edges which together form a receiving-socket, means for opening and closing the guide-plates and an adjustable stop adapted to fit in the socket, of feeding and driving mechanisms, a cutter, a clutch and a connection between the stop and the clutch, whereby when the stop is engaged by the wire the cutter is actuated and the guide-plates caused to release the covered blank.

8. The combination with drawing-rolls and a cutter, of guide-plates having grooves in their contiguous edges to receive the wire, means for opening and closing the guide-plates, a stop carried by one of the guide-plates and intermediate connections whereby when the stop is engaged by the wire the cutter and guide-plates are actuated.

9. The combination with feeding and driving mechanisms, guide-plates having grooves in their contiguous edges and a stop carried by one of the guide-plates, of a plunger carrying a cutter and a cam-head having oblique slots, a lever pivoted to the plunger and engaging the guide-plates and having a cross-pin engaging the oblique slots, a clutch and a connection between the clutch and the stop, so that when the latter is engaged by the wire connection will be made with the driving mechanism and the plunger retracted.

701,876. CRUST-TILE FOR ROOFS. SYLVESTER D. BORN, Indianapolis, Ind. Filed Mar. 14, 1902. Serial No. 92,172. (No model.)

Claim.—1. As a new article of manufacture ready to be applied to a roof without any further preparation, a crust-tile constructed of a sheet of metal bent double in the center and then having its bent edge turned back upon itself so as to form a hook in cross-section and having the leaves of the lower portion opened or spread apart laterally to form flaring flanges, whereby the crust-tile is adapted to be readily placed upon a roof of any pitch; and a single vertical strip having its lower edge turned up to form a hook and having said hook inserted in the hook of the double-

flange piece and the two hooked parts held firmly by being tightly pressed together, the said vertical strip being suitably ornamented.

2. As a new article of manufacture, a metal crust-tile constructed of two sheets of metal, the first of said sheets being bent double in the center and the bent edge then turned to form a hooked edge and the lower flange of said sheet being spread apart laterally to form flaring edges, and said second sheet having its lower edge bent to form a hooked edge which hooked edge is locked with the hooked edge of the first sheet and the two united by pressing the said edges together, the said second sheet having a plurality of transverse stiffening corrugations.

3. As a new article of manufacture, a metal crust-tile constructed of two sheets of metal, the first of said sheets being bent double in the center and the bent edge then turned to form a hooked edge and the lower flange of said sheet being spread apart laterally to form flaring edges, and said second sheet having its lower edge bent to form a hooked edge which hooked edge is locked with the hooked edge of the first sheet and the two united by pressing the said edges together, the said second sheet having a plurality of transverse stiffening corrugations which extend down to the bands forming the joint between said flange and the lower members of the crust-tile.

701,877. CONCRETE COLUMN. ORLANDO W. FORTNER, Worcester, Mass. Filed Nov. 24, 1901. Serial No. 92,378. (No model.)

Claim.—1. A column for building construction, consisting of a solid body of concrete, with a number of concentric tubular bodies of metallic network inclosed in the concrete, so that the maximum amount of metal will be located near the center of the column.

2. A column for building construction, comprising a body and floor-plates of solid concrete, with a number of tubular bodies of metallic network inclosed in the body portion of the column, so that a maximum amount of metal will be located near the center of the column, and metallic-network plates inclosed in the floor-plates of the column.

3. A column for building construction, comprising a cylindrical body portion and floor-plates of solid concrete, and a tubular body of metallic network inclosed in the body portion of the column, and having turned-out ends inclosed in the floor-plates of the column.

701,878. PROCESS OF MAKING PAINT. DAVID J. OULVE, Cincinnati, Ohio. Filed June 24, 1902. Serial No. 79,128. (No machines.)

Claim.—1. The process of making zinc-oxide paint, which consists in treating zinc-white and a suitable vehicle with high-pressure or superheated steam injected into the mass until the mixture has been sufficiently levigated and heated so as to be in a proper condition for straining or other treatment, substantially as specified.

2. The process of making mixtures and combinations of zinc oxide and the proper vehicle consisting in heating and levigating zinc oxide in a tinted dyed or mixed condition and a suitable vehicle with injected high-pressure or superheated steam, until the result has been sufficiently levigated and in a condition to be strained or otherwise treated, substantially as specified.

701,879. VEHICLE-WHEEL. DORIS E. O'BRIEN, Worcester, Mass. Filed Feb. 16, 1901. Renewed Nov. 4, 1901. Serial No. 21,071. (No model.)

Claim.—1. In a vehicle-wheel, the combination with an inner rim to which the spokes are secured, of a supplementary rim removably secured to and bearing against said inner rim; an annular series of double

flat metallic springs removably secured to said supplementary rim; an encircling metal band removably secured to said springs; and an outer composite tread of metal and flexible material, removably secured to said encircling metal band.

2. In a vehicle-wheel, the combination of a rim and encircling metal band, united by an interposed annular series of double flat metallic springs, having projecting stop-arms to prevent undue compression.

3. In a vehicle-wheel, the combination with an inner rim to which the spokes are secured, of a supplementary rim and encircling metal band, united by an interposed series of double flat metallic springs, forming a spring-rim removably secured to said inner rim, said springs having projecting stop-arms to prevent undue compression of said spring-rim.

4. In a vehicle-wheel, the combination with an inner rim to which the spokes are secured, of a supplementary rim and encircling metal band, united by an interposed series of double flat metallic springs, forming a spring-rim removably secured to said inner rim, said springs having projecting stop-arms to prevent undue compression of said spring-rim, and an outer composite tread of metal and flexible material, removably secured to said spring-rim.

5. In a vehicle-wheel, the combination with an inner rim to which the spokes are secured, of a supplementary rim and encircling metal band, united by an interposed annular series of double flat metallic springs, forming a spring-rim removably secured to said inner rim; an outer composite tread of metal and flexible material, removably secured to said spring-rim, and strips of waterproof fabric entirely surrounding said spring-rim, and interposed between it and said inner rim, and between said spring-rim and said outer composite tread.

6. In a vehicle-wheel, the combination with an inner rim to which the spokes are secured, of a removable supplementary rim having annular grooves on its inner surface, and a wide annular channel on its outer surface; an annular series of double flat metallic springs seated in said channel and secured to said supplementary rim, said springs having slots in their outer surfaces and stop-arms to prevent undue compression; an encircling metal band resting on said springs and removably united thereto by double-headed rivets; another metal band encircling the first-named band and held thereto by intermeshing inward indentations in the two bands; strips of waterproof fabric entirely surrounding and including the said supplementary rim, springs and metal bands; spring-wire rings fitting in said annular grooves against said fabric, and thereby holding same in place; and an outer composite tread of metal and flexible material, resting on the fabric-covered metal band, and removably secured thereto.

7. In a vehicle-wheel, the combination with an inner rim to which the spokes are secured, of a removable supplementary rim having annular grooves on its inner surface, and a wide annular channel on its outer surface; an annular series of double flat metallic springs seated in said channel and secured to said supplementary rim, said springs having slots in their outer surfaces and stop-arms to prevent undue compression; an encircling metal band resting on said springs and removably united thereto by double-headed rivets; another metal band encircling the first-named band and held thereto by intermeshing inward indentations in the two bands; strips of waterproof fabric entirely surrounding and including the said supplementary rim, springs, and metal bands; spring-wire rings fitting in said annular grooves against said fabric, and thereby holding same in place; another metal band of greater width than the other bands, having its projecting edges obliquely and outwardly inclined, encircling and resting on the fabric-covered metal band and removably secured thereto; a thick annular band of flexible material conferring in shape to and encircling the said wide metal band; an outer narrow metal band encircling the center of said wide band, and forming therewith the tread of the wheel; and series of curves uniting the wide tread-supporting metal band and the said central narrow outer metal band.

8. In a vehicle-wheel, the combination with an inner rim to which the spokes are secured, of a supplementary rim, and encircling band, united by an interposed series of springs, forming a spring-rim removably secured to said inner rim, and the said supplementary rim having annular grooves on its surface adjacent to said inner rim; strips of waterproof fabric entirely surrounding and including the said supplementary rim, springs and encircling band; and spring-wire rings fitting in said annular grooves against said fabric, and thereby holding the same in place.

701,880. SAWING-MACHINE. FRANK J. PAMA, Chicago, Ill. Filed Aug. 29, 1901. Serial No. 73,088. (No model.)

Claim.—1. A guide for the saw-blade of sawing-machines, comprising substantially a rod adapted to be secured to the saw-blade, an arm pivoted to the frame of the sawing-machine and adjustable with respect thereto, and a guide pivoted upon said arm and adapted to guide the rod in the plane of the saw-blade; substantially as described.

2. In a sawing-machine, a frame, a saw-blade, means for reciprocating the saw, a bearing upon the frame, a guide pivoted in said bear-

ing, a rod clamped to the saw and sliding in said guide and a spring adapted to exert tension through the medium of said rod, upon the free end of said saw; substantially as described.

3. A device for guiding a saw-blade and applying tension thereto, comprising substantially a bearing, a guide pivoted upon the bearing, a rod sliding in said guide and secured to the saw-blade, a spring engaging the guide and a lever connected to the bearing and engaging said spring and adapted by its rotation to tighten or loosen the tension of said spring; substantially as described.

4. In a sawing-machine, a rod, adapted to support the free end of a saw-blade, a guide for said rod, an arm upon which said guide is pivoted; a lever turning upon said pivot connection between the guide and arm, and having clutch-teeth engaging similar teeth upon the arm and a spring connected to the guide and to the bearing, the rotation of said lever in one direction serving to increase the tension upon the guide; substantially as described.

701,881. STREET-SWEEPER. ARTHUR F. PALMER, Waverly, N.Y., and ROBERT L. FERRIS, ARTHUR, Pa., assignors of one-third to James Howard, Cortland, N.Y. Filed Oct. 14, 1900. Serial No. 33,114. (No model.)

Claim.—1. In a sweeper, the combination with the frame, and a revolving brush of a dumping-box receiving the sweepings from the front of the brush, and an auxiliary receiver in the rear of the brush and between it and the box and receiving the sweepings discharged from the rear of the brush.

2. In a sweeper, the combination with a frame and a revolving brush, of a dumping-box receiving the sweepings from the front of the brush, and an auxiliary tilting receiver in the rear of the brush and between it and said box and extending under the box to prevent its dumping, and receiving the sweepings discharged from the rear of the brush.

3. In a sweeper, the combination with a main frame, a revolving brush thereon, and a curtain pendant from the frame, of a dust-pan at the rear end of the brush and a flexible extension thereof between it and the curtain.

4. In a sweeper, the combination with a main frame, a revolving brush thereon and a curtain pendant from the frame in front of the brush, of a dust-pan at the rear end of the brush, and a flexible and inwardly-inclined extension thereof between it and the curtain whereby the sweepings are primarily collected in a window along the edge of said dust-pan.

5. In a sweeper, the combination with a main frame, a revolving brush thereon and a curtain pendant from the frame in front of the brush, of a dust-pan at the rear end of the brush having a tapered flexible and inwardly-inclined extension extending forward to said curtain, whereby the sweepings are primarily thrown onto the incline of the dust-pan and are collected in a window along its edge.

6. In a sweeper, a main frame, a revolving brush and a dust-pan at the rear end of the brush, combined with an elevator-leg substantially horizontal for a part of its length and open along its inner side, of a flexible, inclined dust-pan extension having its outer edge secured to said elevator-leg and dust-pan.

7. In a sweeper, the combination with a revolving brush arranged at an angle with the line of draft, of a dumping-receptacle in the rear of the brush to receive the sweepings, an elevator and once therefrom arranged

to convey and to conduct the sweepings to the receptacle, said once being provided with a depending flexible dust-pan in front of the brush and having an opening in its inner side above the dust-pan to receive the sweepings and to conduct the same to the elevator, said brush and dust-pan being movable vertically for the purpose described.

701,882. DEVICE FOR INDICATING THE RATE OF FLOW OF FLUID. JOHN PATTEN, Baltimore, Md., assignor to Patten Vacuum Ice Machine Company, (successor to the Home Ice Machine Company,) Baltimore, Md., a Corporation of West Virginia. Filed Dec. 8, 1900. Serial No. 34,324. (No model.)

Claim.—1. In a device for measuring the flow of fluid, the combination with a casing having a passage-way for the fluid, of a hollow piston

ton extending into said passage-way and movable longitudinally therein, said piston being open at its inner end and closed at its outer end and having a series of openings in its walls, the consecutive openings in the series being in different positions longitudinally and circumferentially of the piston, and an indicating device operated by the piston for indicating the position of the latter.

2. In a device for measuring the flow of fluid, the combination with a casing having a passage-way for the fluid of a hollow piston extending into said passage-way and movable longitudinally therein, said piston being open at its inner end and closed at its outer end and having a series of openings in its walls, the consecutive openings in the series being in different positions circumferentially and longitudinally of the piston and at such distance apart longitudinally thereof that the bottom of each opening extends below the top of the opening next in succession, and an indicating device operated by the piston for indicating the position of the latter.

3. In a device for measuring the flow of fluid, the combination with a cylinder through which the fluid passes, of a hollow piston extending into the cylinder and movable longitudinally therein, said piston being open at its inner end and closed at its outer end, and having a series of spirally-arranged openings in its walls, and an indicating device operated by the piston for indicating the position of the latter.

4. In a device for measuring the flow of fluid, the combination with a vertically-arranged cylinder through which the fluid passes and an enlarged chamber at the upper end of said cylinder, said chamber having an outlet, of a hollow piston arranged within the cylinder and adapted to move outwardly into the chamber, said piston being open at its inner end and closed at its outer end and having a series of spirally-arranged openings in its walls, and an indicating rod connected to said piston and extending through an opening in the walls of the casing.

701,888. VACUUM-GAGE. JOHN PATTEN, Baltimore, Md., assignor to Patten Vacuum Ice Machine Company, (successor to the Home Ice Machine Company,) Baltimore, Md., a Corporation of West Virginia. Filed Dec. 5, 1900. Serial No. 34,324. (No model.)

Claim.—1. A vacuum-gage comprising a U-shaped tube open at one end, the other end being sealed and having a pocket or cavity out of line with the bore of the tube, in combination with a support in which said gage is revolvably mounted, for the purpose set forth.

2. In a vacuum-gage a U-shaped tube open at one end and having its other end sealed and bent over to provide a pocket or cavity out of line with the bore of the tube, in combination with a support in which said tube is revolvably mounted, for the purpose set forth.

3. A vacuum-gage comprising a U-shaped tube, one arm of which is sealed and formed with a pocket or cavity out of line with the bore of the tube, the other arm of said tube having an enlarged bulbous portion or chamber, in combination with a support in which said gage is revolvably mounted, for the purpose set forth.

4. A vacuum-gage comprising a U-shaped tube one arm of which is sealed and formed with a pocket or cavity out of line with the bore of the tube, the other arm of said tube having an enlarged bulbous portion or chamber and an open end extending upwardly from the chamber at an angle to the lower part of the arm, and a downwardly-inclined tubular support to which said chamber and is revolvably connected.

5. A vacuum-gage comprising a U-shaped glass tube one arm of which is sealed and formed with a pocket or cavity out of line with the bore of the tube, the other arm of said tube having an enlarged bulbous portion or chamber and an open end extending upwardly from the chamber at an angle to the lower part of the arm, a coupling-piece upon said

end, and a tubular support having a downwardly-inclined socket adapted to receive said coupling-piece.

6. A vacuum-gage comprising a U-shaped glass tube, one arm of which is open, the other being sealed and formed with a pocket or cavity out of line with the bore of the tube, and a tubular coupling-piece secured to said open arm, in combination with a support in which said coupling-piece is revolvably connected, for the purpose set forth.

701,884. PACKING-CASE. GEORGE W. POST, Roselle Park, N.J., assignor of two-thirds to Fred C. White, Hawley, Pa., and Oscar T. Post, Roselle Park, N.J. Filed Jan. 30, 1900. Serial No. 31,903. (No model.)

Claim.—1. The combination with a packing-case of buffers comprising two bars with suitably-supported springs between them, the movable bar being offset to one side relative to the one which is attached to the case whereby the latter may be nailed or otherwise attached without interference by the former.

2. The combination in a packing-case of pairs of buffer-bars attached to the interior of the case and loaded and operating one at each side of each corner, a removable frame for the immediate support of the goods located within the case and supported and guided at its corners by the buffers, transverse partitions in said frame whereby it is divided into a series of separate and distinct compartments, and a spring-supported false or interior bottom and a spring-supported false or interior cover.

701,885. GRAIN-DRILL. CHARLES E. FLEWELL, Springfield, Ohio, assignor to the Thomas Manufacturing Company, Springfield, Ohio, a Corporation of Ohio. Filed Apr. 17, 1902. Serial No. 193,570. (No model.)

Claim.—1. In a grain-drill, a combined receiver for grain and fertilizer, comprising an inclined seed or grain conduit, and a substantially vertical fertilizer-conduit, said conduits converging and uniting to form a discharge throat or mouth adapted to be connected with a seed-tube, and said receiver being provided with a partition or extension of the front wall of the fertilizer-conduit, extending downward beyond the point of junction of the two conduits, substantially as described.

2. In a grain-drill, a combined fertilizer and grain or seed receiver comprising an inclined grain or seed conduit, and a substantially vertical fertilizer-conduit, the two converging and uniting to form a discharge throat or mouth adapted to be connected with a seed-tube, the rear wall of the receiver opposite the point of junction being provided with an opening, and said rear wall below said opening being extended outward or rearward, substantially as described.

3. In a grain-drill, a combined fertilizer and grain receiver comprising an inclined grain or seed conduit and a substantially vertical fertilizer-conduit, the two converging and uniting to form a discharge throat or mouth adapted to be connected with a seed-tube, said receiver being provided with a partition extending downward between the conduits at their point of junction, and said receiver having in its rear wall an opening opposite said point of junction, the rear wall being extended outwardly below said opening, substantially as described.

701,886. MACHINE FOR JAPANNING SMALL ARTICLES.
THOMAS A. PERKINS, Syracuse, Conn. Filed Sept. 11, 1901. Serial No. 70,082. (No model.)

Claim.—1. A machine for japanning small articles, comprising a baking-oven, an endless metal belt passing through the oven and having perforations corresponding to the shape of portions of the articles to be treated, and means for imparting movement to the belt, a space being provided at the entrance of the oven for filling the perforations with said articles.

2. A machine for japanning small articles, comprising a baking-oven, an endless metal belt passing through the oven and having perforations corresponding to the shape of portions of the articles to be treated, means for imparting movement to the belt, a space being provided at the entrance of the oven for filling the perforations with said articles, and a support for the belt while being filled.

3. A machine for japanning small articles, comprising a baking-oven, an endless metal belt passing through the oven and having perforations corresponding to the shape of portions of the articles being treated, pulleys over which the belt passes, one of said pulleys being located at a distance from the entrance end of the oven to afford a space for filling the perforations of the belt with the articles, and a support for the belt between the said entrance end of the oven and the pulley.

4. A machine for japanning small articles, comprising a baking-oven, an endless metal belt passing through the oven and having perforations corresponding to the shape of portions of the articles being treated, pulleys over which the belt passes, one of said pulleys being at a distance from the entrance end of the oven to afford a space for filling the perforations of the belt with the articles, and the other pulley serving as means for partially ejecting the articles from the perforations after leaving the oven.

5. A machine for japanning small articles, comprising a baking-oven, an endless metal belt passing through the oven and having perforations corresponding to the shape of portions of the articles being treated, pulleys over which the belt passes, one of said pulleys being at a distance from the entrance end of the oven to afford a space for filling the perforations of the belt with the articles, and the other pulley serving as means for partially ejecting the articles from the perforations after leaving the oven, and a rotary brush adjacent to the under side of the last-mentioned pulley to dislodge the articles which have been partially ejected.

6. A machine for japanning small articles, comprising a baking-oven, an endless metal belt passing through the oven and having perforations corresponding to the shape of portions of the articles to be treated, means for imparting movement to the belt, a space being provided at the entrance of the oven for filling the perforations with said articles, means for supporting the belt while being filled, and means within the oven for guiding and supporting the edges of the belt.

7. A machine for japanning small articles, comprising a baking-oven, an endless metal belt passing through the oven and having perforations corresponding to the shape of portions of the articles to be treated, means for imparting movement to the belt, a belt-cleaning tank outside of the oven, and means for guiding the belt through said tank.

8. In a machine of the character described the combination with an endless perforated metal belt and means for driving the same, of guides in which the edges of the belt travel, cross-pieces 14 by which pairs of guides are connected, means for holding said guides in place while permitting lateral movement thereof and a baking-oven through which the belt passes.

701,887. REMOVABLE HANDLE. CHARLES M. PERKINS, Lakewood, N.J. Filed Mar. 2, 1902. Serial No. 94,488. (No model.)

Claim.—A handle of the character described comprising bows or rails connected together at their highest point and spread apart at their ends and provided with lugs, shoulders projecting inwardly from said bows or rails immediately above said lugs, and means for holding the ends curved apart, substantially as described.

701,888. CUTTING AND PASTING DEVICE FOR CIGAR-WRAP PING MACHINES. EMANUEL PERIN, New York, N.Y. Filed Apr. 24, 1901. Serial No. 87,283. (No model.)

Claim.—1. In a cigar-rolling machine, the combination of a knife for slitting the end of the wrapper, means for operating the same, and means for applying the paste to the wrapper between the slit and the end of the wrapper, substantially as described.

2. In a cigar-rolling machine, the combination of a knife for slitting the end of the wrapper, means for operating the same, and means whereby the action of the cutter will automatically cause the paste to be applied to the wrapper between the slit and the end of the wrapper, substantially as described.

3. In a cigar-rolling machine, means for producing an angular slit or cut in the end of the wrapper as a single operation, substantially as described.

701,889. STORAGE-BATTERY ELECTRODE. JOHANNES VON DER POTTENBURG, Charlottenburg, Germany. Filed Apr. 30, 1902. Received Apr. 17, 1902. Serial No. 100,420. (No model.)

Claim.—An improved storage-battery electrode comprising a conducting-frame independently-removable cross-pieces of non-conducting material carried by the frame and having perforated portions projecting on each side thereof, perforated protecting-strips, active material interposed between said strips, and removable vertical elastic bars held in said perforations in the cross-pieces adapted to press the protecting-strips against the active material, substantially as described.

701,890. BICYCLE-SADDLE. JOHN H. PASVOORT, Buffalo, N.Y. Filed Dec. 12, 1900. Serial No. 74,894. (No model.)

Claim.—1. A bicycle-saddle the seat or body portion of which consists of plates separated or divided transversely of the middle and which together form the support for carrying the weight of the rider, in combination with means to support said plates independently and elastically from a common support, substantially as set forth.

2. A bicycle-saddle, the seat or body portion of which consists of two plates separated or divided transversely of the middle which together form the support for carrying the weight of the rider, in combination with a suitable spring or springs divided at one point, one of said plates being curved to said spring or springs at one end of said division and the other plate at the other end of said division, and means to secure said spring or springs to a middle-post, substantially as set forth.

3. A bicycle-saddle, the seat or body portion of which consists of two plates separated or divided transversely of the middle which together form the support for carrying the weight of the rider, in combination with a suitable spring or springs divided at one point, one of said plates being curved to the spring or springs at one end of said division and the other plate at the other end of said division, means to secure said spring or springs to the middle-post at or about opposite the point of said division, and two pads which together are adapted to fit over said plates, each spanning both plates and each being adjustably mounted thereon, substantially as set forth.

4. In a bicycle-saddle, the combination of a longitudinal supporting-spring having its upper portion divided transversely into front and rear members, transverse front and rear plates mounted on the front and rear members of said spring, respectively, and flexible pads mounted side by side on said plates and each resting upon both of said plates, substantially as set forth.

5. In a bicycle-saddle, the combination of a pair of transverse supporting-plates arranged one in front of the other, flexible pads mounted on said plates, and a pair of longitudinal supporting-springs for said plates, each having a main lower member and a divided upper member, the sections of which are provided at their inner ends with outwardly and laterally extending branches which are secured to the under side of said transverse plates, substantially as set forth.

701,891. ROTARY BORING APPARATUS. WLASTYAW PRUS-SKOWSKI, Schudalen, Austria-Hungary. Filed June 12, 1900. Serial No. 80,084. (No model.)

Claim.—1. The combination with a tubular bore-rod and a cylinder on the end thereof; of a tool-carrier in said cylinder provided with ports, and a tool on the end of the carrier, and a rotatable valve co-operating with the ports in the carrier to alternately cut off and admit the supply of water through the carrier and cause the inertia of the moving column to drive it and the tool, substantially as set forth.

2. The combination with a tubular bore-rod and a cylinder on the end thereof; of a hollow piston in the cylinder and provided with ports inclined to the direction of flow of water through it, a rotatable valve provided with ports inclined in a direction opposite to those in the piston and located within the piston whereby the current of water is automatically cut off to cause the inertia of the moving column to drive the piston and tool, and a spring to return the piston into operative position, substantially as set forth.

3. The combination with a tubular bore-rod and a cylinder on the end thereof; of a hollow piston in the cylinder and provided with ports in its end inclined in the direction of flow of water, a disk valve pivoted within the piston and provided with radial ports inclined to the direction of flow of water and opposite to those in the piston, and a coil-spring to return the piston to operative position, substantially as set forth.

4. The combination with a tubular bore-rod and a tubular tool-carrier, open at its lower end and fitted to reciprocate in the lower end of said rod, said carrier provided with a series of ports in communication with the bore-rod above the carrier; of a valve having corresponding ports and controlling said carrier-ports, said valve organized to revolve under the action of the fluid under pressure in the bore-rod whereby the pressure on the carrier is alternately reduced and re-established, and means acting to move the carrier against the reduced pressure, for the purpose set forth.

5. The combination with a revolvable tubular bore-rod and a tubular tool-carrier open at its lower end, and fitted to revolve with and to reciprocate in the lower end of said rod, said carrier provided with a series of ports in communication with the bore-rod above the carrier; of a valve having corresponding ports and controlling said carrier-ports, said valve organized to revolve under the action of a fluid under pressure in the bore-rod whereby the pressure on the carrier is alternately reduced and re-established, and means acting to move the carrier against the reduced pressure, for the purpose set forth.

6. The combination with a bore-rod having a fluid-passage extending therethrough, a piston-cylinder at the lower end of said rod and in communication with its fluid-passage, said cylinder having fluid-exhaust ports, and a piston working in said cylinder and carrying the boring-tool; of a valve having corresponding ports, and controlling the exhaust-ports in the cylinder, said valve organized to revolve under the pressure acting on the piston-carrier, whereby said pressure is alternately reduced and re-established, and means acting to move the piston against the reduced pressure, for the purpose set forth.

7. The combination with a revolvable bore-rod and a tool-carrier

head to reciprocate in the lower end of said rod, said carrier organized to move in one direction under the action of the inertia of a moving column of fluid; of means for alternately and automatically reducing and retarding the pressure acting on the carrier, and means for moving said carrier in an opposite direction at each reduction, and a casing secured to the bore-rod open at its lower end and provided at said end with oppositely-arranged slots through which the boring-tool projects to cause the same to revolve with the bore-rod without interfering with the reciprocations of said tool, substantially as and for the purpose set forth.

701,892. INSULATING-PAINT. LEONARD M. RANDOLPH, Newark, N. J., assignor of six-tenths to Edward C. Bruno and Lawrence F. Bruno, Brooklyn, N. Y. Filed Sept. 8, 1901. Serial No. 74,662. (No specimens.)

Claim.—1. The jaspersing or insulating compound herein specified, consisting of varnish residues, powdered peat and naphtha or similar solvent, substantially as set forth.

2. The jaspersing or insulating-paint herein specified and consisting of varnish residues, about twenty-five per cent. of powdered peat, and naphtha or similar solvent sufficient to thin the same down to the desired consistency, substantially as set forth.

3. The method herein specified of manufacturing a jaspersing or insulating-paint, consisting in taking a waste product from the manufacture of varnish, jaspers and chollas, and known as varnish residues, heating the same hot and straining the same through cloth or similar material for the removal of various foreign substances, adding to the hot strained varnish residues about twenty-five per cent. of powdered peat, stirring the same thoroughly to form a homogeneous mass, and adding thereto naphtha or similar solvent material for the purpose of thinning the same down to the desired consistency, substantially as set forth.

701,893. CARPET-SWEEPER. SILVANO J. RYBOLIN, Saginaw, Mich. Filed July 1, 1901. Serial No. 64,764. (No model.)

Claim.—1. In combination with a casing carrying pairs of horizontally-adjustable wheels yieldingly pressed toward each other; a brush-spindle engaged and supported by said wheels; a vertically-adjustable brush-adjuster having a horizontal lower bearing-face permitting horizontal movement of the brush-spindle, and openings in said casing larger than said spindle for the purpose set forth.

2. In a carpet-sweeper, the combination with the casing, of a pair of parallel shafts extending through horizontal slots in the ends of the casing and carrying wheels on their outer ends; leaved springs secured as one end to the casing and pressing the shafts toward the center line of the sweeper; a brush-spindle reduced in diameter near its ends; rollers housed on the spindle and yieldingly held between the wheels above their center line; a pair of vertically-adjustable brush-adjusters having horizontal spring members to yieldingly press the upper side of said spindles; and openings in the casing for the passage of the spindles, said openings being larger than the spindles, the brush being supported and rotated independent of the casing.

3. In combination with a carpet-sweeper casing having wheel-shafts mounted in horizontal slots and yieldingly pressed toward the center line of the casing; a brush-spindle extending through openings in the casing, said openings being larger than the spindle to permit its independent horizontal and vertical movement; a vertically-adjustable brush-adjuster near each end of the spindle, comprising a vertical rod bent horizontally near its lower end to form a horizontal spring member; said brush-spindle being held in place and not in contact with the casing by the combined action of the wheels and the spring brush-adjuster, for the purpose set forth.

4. In a carpet-sweeper, a rotatable brush having the ends of its spindle supported by the combined action of the horizontally-yielding wheels and a vertically-yielding spring member above the spindle; whereby the brush-spindle is capable of moving with the wheels and in contact with them in both a horizontal and vertical direction, substantially as described.

5. In a carpet-sweeper having horizontally-yielding wheels spring-pressed toward each other, the combination of a brush-spindle having rollers engaged between said wheels above their center line, and a downwardly-pressing adjustable spring having a horizontal lower face to take the upward thrust of the spindle, said spindle passing freely through the casing and being supported solely by the combined action of the wheels and the spring, substantially as described and for the purpose set forth.

701,894. STAIR-ROD FASTENER. WILLIAM RICHARDS, Cambridge, Mass. Filed Aug. 24, 1901. Serial No. 72,191. (No model.)

Claim.—A stair-rod fastener, consisting of an attaching bracket member having angularly-related arms, the outer end of one arm being provided with an overhanging terminal keeper, which is provided with a pendant projection, and a springing clip member having one end pivotally connected to the other bracket-arm, and its opposite free end constructed to fit within the keeper and provided in its upper face with a socket or depression for the reception of the pendant projection of the keeper.

701,895. BROOM. BRIAN ROBERTSON, Fremont, Ark. Filed Mar. 27, 1902. Serial No. 108,292. (No model.)

Claim.—1. The combination with the broom-head and the handle extending therethrough, of a base-wire inserted through the end of the handle and projecting beyond the edge of the broom-head, internally-threaded sleeves held by the ends of said wire, fastening-bolts fitted in the ends of said sleeves, and clamping-wires mounted on said bolts and passing across the face of the broom-head.

2. The combination with the broom-head and the handle, of a base-wire inserted through the handle and projecting beyond the edge of the broom-head, clamping-bolts supported by the ends of said wire, clamping-wires carried by said bolts and passing across the broom-head, supporting-frames secured to the handle above the broom-head, passing therefrom to and encircling the clamping-bolts, and provided with hooks below the bolts, and brace-wires attached to the handle above the broom-head and diverging downward therefrom and engaging the hooks on the supporting-frames.

701,896. ELECTRICAL PROTECTOR. CHARLES A. BELLE, Chicago, Ill., assignor to Bell Electric Company, Chicago, Ill., a Corporation of Illinois. Filed Aug. 1, 1900. Serial No. 25,541. (No model.)

Claim.—1. The combination with structurally-separate heat-generating and heat-responsive devices of a power device upon which the heat-generating device is mounted, and the means for controlling the circuit operable by the power device, substantially as set forth.

2. The combination with structurally-separate heat-generating and heat-responsive devices of a power device upon which the heat-generating device is mounted, and means for opening the circuit upon the generation of heat in the heat-generating device sufficient to operate the heat-responsive device, substantially as described.

3. The combination with a base of a spring secured thereto and having an arm adapted to swing upwardly, a heat-generating device mounted upon the end of said spring, a support arranged at the end of the spring and provided with a heat-responsive device adapted to cooperate with the heat-generating device and positioned over the spring so as to hold the same against the upward movement, and circuit-controlling means operable by the spring upon its release, substantially as described.

4. The combination with a base of a spring secured thereto and having an arm adapted to swing upwardly, a heat-generating device mounted upon the end of said spring, a support arranged at the end of the spring and provided with a heat-responsive device adapted to cooperate with the heat-generating device and positioned over the spring so as to hold the same against the upward movement, and means for breaking the circuit operable by the spring upon its release, substantially as described.

5. The combination of a base, a spring secured to the base and having an arm adapted to swing upwardly, a coil of fine wire mounted upon the end of said spring-arm, a support secured to the base and provided with a mass of heat-responsive material which is arranged above the coil of fine wire so that the generation of heat in the latter will cause or break the mass of heat-responsive material, and means for controlling the circuit upon the release of the spring.

6. The combination of a base, a spring secured to the base and having an arm adapted to swing upwardly, a coil of fine wire mounted upon the end of said spring-arm, a support secured to the base and provided with a mass of heat-responsive material which is arranged above the coil of fine wire so that the generation of heat in the latter will cause or break the mass of heat-responsive material, and means for opening the circuit upon the release of the spring.

7. The combination of a spring provided with contacts and also provided with a coil of fine wire mounted with said contacts; contact-jaws cooperating with said contacts; and a heat-responsive device arranged to hold the spring in the position in which its contacts engage the contact-jaws and connected with the coil of fine wire on the spring so that the generation of heat in the latter operates the heat-responsive device and allows the same to release the spring.

8. The combination of a spring carrying a contact; a contact-jaw cooperating with said contact; a heat-generating device; and a heat-responsive device cooperating to hold the spring in the position in which its contact engages the contact-jaw, and to release the same upon the generation of heat in the heat-generating device.

9. The combination of a spring carrying a pair of contacts, and having a coil of wire arranged at its free end; contact-jaws cooperating with the contacts carried by the spring; a stick or block of fusible or softenable material held in position to engage the coil of wire at the end of the spring, and to release the spring upon generation of heat in said coil.

10. The combination of a pair of cooperating electrodes; a spring upon which one of said electrodes is mounted; means whereby the spring is held in position to maintain its electrodes normally separated from but in close proximity to the other electrode; and means for releasing the spring so as to allow it to operate and separate its electrodes widely from the other electrode.

11. The combination of a pair of electrodes, a spring upon which one of said electrodes is mounted; a circuit-breaking device arranged to maintain the circuit normally closed and to open the same upon the passage therein of an unduly strong current, the said circuit-breaking device being also arranged to hold the spring normally in position to maintain the electrodes thereon normally away from but in close proximity to the other electrode, and to separate the same widely upon its operation to break the circuit.

12. The combination of a spring carrying a pair of contacts, one of which is insulated from the spring, and the other of which is connected electrically therewith; a heat-generating or concentrating coil of wire carried at the end of the spring and connected with said contacts; a carbon electrode also carried by the spring; a ground electrode cooperating with the carbon on the spring; a stick or mass of fusible or softenable material engaging the coil of wire on the spring so as to hold the same in a lowered condition normally, but to release the same upon the passage in the coil of an unduly strong current; and a support for said stick or mass of fusible or softenable material.

701,897. CORN HUSKER AND SHREDDER AND HUSK-SEPARATOR. ALBERT BERNHARD, Milwaukee, Wis., assignor to Rosenthal Husker Company, a Corporation of Wisconsin. Filed June 14, 1901. Serial No. 64,694. (No model.)

Claim.—1. The combination of a lower frame, an upper frame removably fitted thereon, means for causing the material fed into the machine to pass from one end of said machine toward the opposite end thereof, rotatable feed-rolls at the end of the machine adapted to receive the material as fed therebetween, rotatable cutting and shredding mechanism adapted to act on the material as it leaves the feed-rolls, and means for conveying material from the machine, after said material has been acted upon by the cutting and shredding mechanism.

2. The combination of a frame, cutting mechanism carried by the frame, rotatable husking-rollers journaled in the frame, a platform below the husking-rollers and provided with a series of open spaces through which chaffed corn is adapted to pass, and an endless conveyor running over said platform and adapted to convey to the cutting mechanism the material passing between and falling below the husking-rollers.

3. The combination of a frame, a main drive-shaft mounted therein at the forward end of the frame and having a toothed wheel thereon, an auxiliary shaft having a toothed wheel engaged by the toothed wheel of the main shaft, and also having a beveled gear-wheel mounted thereon, husking-rollers journaled in the frame, the corresponding ends of the journals of said rollers provided with intermeshing gear-wheels, and the opposite journal of one of the rollers provided with a beveled gear-wheel meshing with the beveled gear-wheel of the auxiliary shaft, an endless conveyor below the husking-rollers, feed-rollers at the forward end of the conveyor, said feed-rollers being geared together, and the journal of one of said rollers provided with a pinion, said pinion being in mesh with a toothed wheel on the drive-shaft, a system of gearing between said pinion of the feed-roll and the forward roll of the conveyor mechanism, cut-

ting and shredding mechanism mounted on the main shaft, a fan-casing below the cutting and shredding mechanism, a fan within said casing, and a belt connection between the fan-shaft and the main shaft.

4. The combination of a frame, rotatable husking-rollers journaled therein, the forward portions of said rollers provided with means for separating the stalks from the ears of corn, and the remaining portions of said rollers provided with husking means, a hopper at the upper portion of the frame, and a board arranged above the rollers and extending at a downward incline from the rear end of the hopper toward the front and thereof for such a distance as to compel, in the first place, the grouping by the separating ends of the rollers of the ends of the cornstalks which project beyond the inclined board, and said inclined board thereby also adapted to tilt the stalks toward a vertical position.

5. The combination of an upper frame, means for causing the material fed into the machine to pass from one end of said machine to the other, rotatable feed-rolls carried by the upper frame, and arranged at one end of said frame, and adapted to receive therebetween the material fed through the machine, rotatable cutting and shredding mechanism carried by the upper frame and arranged in said upper frame in position to act on the material as it leaves the feed-rolls, a lower frame to which the upper frame is removably fitted, and means for conveying the material from the machine, after said material has been acted upon by the cutting and shredding mechanism, said means being carried by the lower frame.

701,898. ARRANGEMENT FOR SHIFTING THE POINTS OF TRAMWAY OR RAILWAY LIMB. GEORGE E. ROSS, Glasgow, Scotland. Filed Feb. 12, 1902. Serial No. 65,734. (No model.)

Claim.—1. The combination with the car and the point to be shifted, of a movable plate having cross-grooves on its upper surface, a rocking arm supporting the plate, a pin supporting the arm, a box containing the arm and plate, a rod connecting the arm with the point and a point-chifter fitted to the car and adapted to engage with one or other of the grooves of the plate, substantially as described.

2. The combination with the car and the point to be shifted, of a movable plate having cross-grooves on its upper surface, a rocking arm supporting the plate, a pin supporting the arm, a box containing the arm and plate, a lag on the arm, a connecting-rod jointed at one end to the lag and at the other end to a tongue on the point, and a point-chifter fitted to the car and adapted to engage with one or other of the grooves of the plate, substantially as described.

3. The combination with the car and the point to be shifted, of a movable plate having cross-grooves on its upper surface, a rocking arm supporting the plate, a pin supporting the arm, a box containing the arm and plate, said box being broad and flat at its upper end and narrow and tapered at its lower end, a drain-hole in the bottom of the box, means for limiting the movement of the arm, means for connecting the plate to the

point and a point-chifter on the car which is adapted to engage with one or other of the grooves of the plate, substantially as described.

4. The combination with the car and the point to be shifted, of a movable plate having cross-grooves on its upper surface, a rocking arm supporting the plate, a pin supporting the arm, a box containing the arm and plate, said box being broad and flat at its upper end and narrow and tapered at its lower end, a drain-hole in the bottom of the box, guide-openings in the sides of the box, guideways leading to and from the box, a cover for the box, a guide-slot made across the cover in the same line as the guideways, means for limiting the movement of the arm, means for connecting the plate to the point and a point-chifter on the car which is adapted to engage with one or other of the grooves of the plate, substantially as described.

701,899. REIN-HOLDER. GLENN BATHURST, Dura, Tenn. Filed Mar. 31, 1902. Serial No. 100,855. (No model.)

Claim.—A rein-holder comprising a supporting-plate, cam-jaws mounted upon one side of the plate, one of said jaws being provided with a finger-piece, shafts or pistons connected to the jaws and projecting through the plate, toothed segments connected to said shafts or pistons on the opposite sides of the plate, and a loop-wire spring secured to the plate and having its free ends connected to the segments and provided with spring-cells, the said free ends of the spring normally tending to force the segments to a position in which the segments act to force the jaws closed, substantially as set forth.

701,400. MAGAZINE PLATE-HOLDER FOR CAMERAS. JOHN C. F. SCHAFER, Mount Pleasant, Ill. Filed Apr. 26, 1902. Serial No. 14,472. (No model.)

Claim.—1. In a magazine plate-holder for cameras, the combination of a plate-magazine, a case slidable on said plate-magazine, a handle on said case, a hook mounted on said case, and a hook-operating device contiguous to said handle, as set forth.

2. In a magazine plate-holder for cameras, the combination of a plate-magazine, a case slidable in said plate-magazine, a case slidable on said plate-magazine, a handle on said case, a hook mounted on said case, a hook-operating device contiguous to the handle on said case, means for shifting said case in said case, and means for returning said case to said plate-magazine, as set forth.

3. In a magazine plate-holder for cameras, the combination of a plate-magazine, a case slidable on said plate-magazine, a handle on said case, a hook mounted on said case, a slide contiguous to said handle, an arm connected with said slide and engaging with said hook, a spring acting against said hook, a shifting-frame mounted on said case, and a spring actuating said shifting-frame, as set forth.

4. In a magazine plate-holder for cameras the combination of a case, a plate-hook mounted on said case and having an extension, a hook-disengaging device operative from the outside of said case, a plate-magazine on which said case is slidable and having a housing to accommodate the extension of said hook, means for limiting the movement of said case and sheaths within said plate-magazine with which said plate-hook engages, as set forth.

5. In a magazine plate-holder for cameras, the combination of a plate-magazine, a case slidable on said plate-magazine and having compartments, a plate-shifting frame mounted in one compartment of said case and a spring mounted in the other compartment of said case and operatively connected with said plate-shifting frame, and a plate-hook on said case in cooperative relation to said plate-shifting frame, as set forth.

6. In a camera, the combination of a camera-box having an opening adapted to accommodate a slidable case, a housing mounted in said camera-box, a plate-magazine within said housing and provided with a ledge, securing devices connecting said plate-magazine with the camera-box, and a case slidable on said plate-magazine and having a ledge which engages with the ledge on the plate-magazine to limit inward movement of said case and engages with a wall of said camera-box to limit the outward movement of said case, as set forth.

7. In a magazine plate-holder for cameras, the combination of a plate-magazine, a housing, and a case slidable between said plate-magazine and housing, all three being separable from each other for the removal of and insertion of plates, as set forth.

8. In a camera, the combination of a camera-box, a housing mounted on said camera-box, a plate-magazine housed in said housing and detachably connected with said camera-box, and a case slidable on said plate-magazine and having a sliding movement within said housing, limited in one direction, as set forth.

9. In a magazine plate-holder for cameras, the combination of a housing, a plate-magazine housed in said housing, and a case slidable on said plate-magazine and having sliding movement within said housing, limited in one direction, said plate-magazine and case being withdrawable from said housing, as set forth.

701,401. COMBINED PACKING AND DISPLAYING BOX. WILLIAM SCHUBERT, Brooklyn, N. Y. Filed Jan. 11, 1902. Serial No. 88,297. (No model.)

Claim.—The combination with a box, having its front wall hinged at its bottom edge to the front edge of the box-bottom, of an L-shaped strip fastened each to the inner surface of the front wall and of the rear

wall, the horizontally-projecting leg of each strip being provided with notches, substantially as described.

701,403. FOUNTAIN-PEN. HERMAN SCHWARTZ and IRVING SILVERMAN, New York, N. Y. Filed Mar. 10, 1902. Serial No. 97,490. (No model.)

Claim.—1. A brush-holder comprising a reservoir adapted to receive a brush, a socket located wholly within the reservoir, a rod to stay the socket secured to the wall of the reservoir and to the socket, and means carried by said socket to engage the handle positively, substantially as shown and described.

2. A brush-holder comprising a reservoir adapted to receive a brush, a socket located wholly within the reservoir, a stay-rod secured to the wall of the reservoir and to the socket, a nut secured to the side of the socket, and a screw extended through the wall of the reservoir and through said nut and the wall of the socket to clamp the handle within the socket, substantially as shown and described.

701,408. STEAM-GENERATOR. WILLIAM SHARPE and DAVID CRAWFORD, Glasgow, Scotland. Filed Jan. 14, 1902. Serial No. 98,942. (No model.)

Claim.—1. In steam-generators, the combination of an inclined nest of water-tubes having sectional headers connected to each end thereof, a fire-tube boiler having a front and back plate connected thereto, circulating-tubes connected to said headers and extending into said front and back plates of the fire-tube boiler, a pair of dished nozzles having their dished portions in contact with one another with tubes extending through said dished portions, and a drum carried by the upper nozzle, substantially as described.

2. In steam-generators, the combination of an inclined nest of water-tubes, sectional headers for the tubes, circulating-tubes connected with the headers, a superposed fire-tube boiler, and plates on the boiler, outwardly-bulged parts made in the end plates for the reception of the said circulating-tubes, nozzles *r, s*, secured to the boiler and a drum *t* secured to the nozzles, substantially as set forth.

701,404. ROTARY ENGINE. SYLVANUS C. SHARP, Haverhill, Mass. Filed Feb. 24, 1902. Serial No. 98,943. (No model.)

Claim.—1. In a rotary engine, a casing; heads closing the ends of the casing; a shaft mounted in said heads; a piston mounted upon said shaft between said heads and forming a steam-chamber; a wing extending from said piston and engaging the inner surface of said casing; a rocking abutment of cylindrical form mounted in a cylindrical opening and extending into said chamber and engaging the periphery of said piston; a cam on the outer end of said shaft; a second cam on the outer end of the abutment-shaft, there being a projection on the first-mentioned cam and a cut-away portion of the second-mentioned cam, so that when the piston rotates, the abutment will be rocked out of the way of said wing; and a spring for returning said abutment to its normal position; substantially as specified.

2. In a rotary engine, a casing; heads closing the ends of the casing; a shaft mounted in said heads; a piston mounted upon said shaft between said heads and forming a steam-chamber; a wing extending from said piston and engaging the inner surface of the casing; a rocking abutment mounted in a cylindrical opening and extending into said chamber and engaging the periphery of said piston, said rocking abutment having a cut-away portion to allow said wing to pass, and said rocking abutment having a bearing-surface to form a bearing-surface to engage the periphery of the piston and form a stop to limit the backward motion of the abutment; a cam on the outer end of said shaft; a second cam on the outer end of the abutment-shaft, there being a projection on the first-mentioned cam, and a cut-away portion on the second-mentioned cam, so that when the piston rotates, the abutment will be rocked out of the way of said wing; and a spring for returning said abutment to its normal position with said bearing-surface against the periphery of the piston, substantially as specified.

3. In a rotary engine, a casing; heads closing the ends of the casing; a shaft mounted in said heads; a piston mounted upon said shaft between said heads and forming a steam-chamber; a wing extending from said piston and engaging the inner surface of the casing; a rocking abutment extending into said steam-chamber and engaging the periphery of the piston; means of rocking said abutment out of the way of said wing; a rocking valve for admitting steam to said chamber; a spring connecting one end of the valve to the frame, the tension of said spring being exerted to hold the valve closed; a tubular arm rigidly fixed upon the outer end of the shaft of the valve, the upper end of said arm being transversely slotted; an adjustable stop projecting from the frame and engaging said arm to resist the tension of said spring; a slide mounted in said tubular arm; a pin extending outwardly from said slide through said slot; a cam-wheel fixed upon the end of the shaft and having a shoulder to engage the outer end of said slide, and a second shoulder to release said slide so that when said cam-wheel strikes said slide, the valve will be opened; a lever pivoted to the frame and having a slot in one end to receive said pin; a second lever pivoted in position to engage the opposite end of the first-mentioned lever; and a governor mounted in position to have its sliding link engage said second lever as required to move said slide in and out in said tubular arm by the action of the governor, thus regulating the valve, substantially as specified.

701,405. EJECTING DEVICE FOR STAMPING-MACHINES. JOHN SHERRIFF, Greenwich, London, England, assignor to Archibald White Macintosh, London, England. Filed Feb. 17, 1902. Serial No. 98,957. (No model.)

Claim.—1. In a stamping or like machine, the combination with a reciprocating die-carrying plunger, of a device for ejecting stamped articles comprising an oscillatory spindle approximately parallel to the line of movement of the plunger, an ejector-arm projecting from the spindle, an actuating-arm projecting from the plunger, and a spindle-oscillating connection between the actuating-arm and spindle.

2. In a stamping or like machine, the combination with a reciprocating die-carrying plunger, of a device for ejecting stamped articles comprising an oscillatory spindle approximately parallel to the line of movement of the plunger, an ejector-arm projecting from the spindle, an actuating-arm projecting from the plunger, and a spindle-oscillating connection between the actuating-arm and spindle comprising a projection on one part engaging a cam-groove in the other.

701,406. CUT-OFF-VALVE MECHANISM. FRANKLIN T. BROWN, Corvallis, Minn., assignor to one-half to Thomas K. Jones, Corvallis, Minn. Filed July 16, 1901. Serial No. 68,831. (No model.)

Claim.—1. The combination of a reciprocating valve-stem, right and left hand screw-cleaves splined thereon, means to adjust said screw-cleaves on said valve-stem, means to turn the latter, and cut-off valves engaged and operated by said screw-cleaves, whereby said cut-off valves may be moved longitudinally in opposite directions by turning said valve-stem, for the purpose set forth, substantially as described.

2. The combination of a reciprocating valve-stem, right and left hand screw-cleaves splined thereon, means to adjust said screw-cleaves on said valve-stem, means to turn the latter, cut-off valves engaged and operated by said screw-cleaves, whereby said cut-off valves may be moved longitudinally in opposite directions by turning said valve-stem, and a centrifugal mechanism and connections between the same and said valve-stem, to automatically turn the latter, substantially as described.

3. The combination of a reciprocating screw-threaded valve-stem, right and left hand screw-cleaves splined thereon, but not engaged by the screw-thread thereof, adjusting-nuts on said threaded valve-stem to adjust said screw-cleaves, and cut-off valves engaged by said right and left hand screw-cleaves, for the purpose set forth, substantially as described.

4. In an engine, the combination of cut-off valves, a reciprocating reversible valve-stem, to move said valves reversely, for the purpose set forth, a spring to turn said valve-stem in one direction, a centrifugal mechanism to turn said stem in the reverse direction, and means to vary the power of said spring, substantially as described.

5. In an engine, the combination of cut-off valves, a reciprocating reversible valve-stem, to move said valves reversely, for the purpose set forth, a spring to turn said valve-stem in one direction, a centrifugal mechanism to turn said stem in the reverse direction, and means to vary the power of said spring, substantially as described.

6. In an engine, the combination of cut-off valves, a reciprocating reversible valve-stem, to move said valves reversely, for the purpose set forth, and means, automatically operated, on an abnormal increase of

speed of the engine, to turn said stem and cause said valves to cut off the supply of steam to the cylinder, substantially as described.

7. In an engine, the combination of cut-off valves, operative on the steam and exhaust ports of the cylinder, a speed mechanism to adjust said valves automatically, a belt to drive said speed mechanism, a normally idle element supported by said belt, and connections between said normally idle element and said valves, to operate the latter when said normally idle element is released by said belt, substantially as described.

701,407. BALING-SLIP AND BLANK THEREFOR. SAMUEL BROWN and LAUREN E. BROWN, Wilmington, Del. Filed Feb. 8, 1901. Serial No. 68,862. (No model.)

Claim.—1. As a new article of manufacture, a roll of paper for use in the making of check baling-slips, said roll consisting of two or more webs of paper wound up together in a single roll, two or more of the webs being pasted together on longitudinal lines and one or more of the webs being scored and ruled longitudinally.

2. As a new article of manufacture, a roll of paper for use in the making of check baling-slips, said roll consisting of two or more webs wound up together in a single roll, one or more of the webs being scored longitudinally, and one or more of them being scored and ruled longitudinally.

3. As a new article of manufacture, a roll of paper for use in making baling-slips, said roll consisting of two or more webs wound up together in a single roll and one or more of the webs having continuous longitudinal ruled lines.

4. As a new article of manufacture, a roll of paper for use in making baling-slips, said roll consisting of two or more webs wound up together in a single roll, one or more of the webs being scored longitudinally.

5. As a new article of manufacture, a roll of paper for use in making baling-slips, said roll consisting of two or more webs wound up together in a single roll and scored longitudinally on lines not overlying each other in different webs.

6. As a new article of manufacture, a roll of paper for use in making baling-slips, said roll consisting of two or more webs scored longitudinally and having lines ruled thereon to identify the score-lines.

701,408. SPRING-BED. SAMUEL L. GURVIN, New York, N. Y. Filed Mar. 4, 1901. Serial No. 68,867. (No model.)

Claim.—A collapsible spring-bed, consisting of a plurality of coils extending transversely to the direction of collapse, each coil having hooked ends adapted to engage the rails of a bedstead, and a vertical portion between said ends, ends on the coils, folding links pivoted to and supported by said ends, and arranged in the direction of collapse, said ends being composed each of a shank adapted to be attached to the coil and to support a link above and out of contact with the same, and a pivot extending upwardly from said shank, and bed-springs supported on said coils, substantially as set forth.

701,409. APPARATUS FOR COPYING DOCUMENTS, DRAWINGS, &c. ROBERT BURNHAM, London, England. Filed Jan. 12, 1902. Serial No. 68,872. (No model.)

Claim.—1. An apparatus for copying documents, drawings and the like comprising a frame carrying the stencil-sheet a bed on which the paper to receive the impression is laid, and two pairs of links connecting the frame with the bed, the pairs being of unequal effective length in order to cause the one end of the frame to rise more rapidly and to a greater extent than the other and thereof, as set forth.

2. An apparatus for copying documents, drawings and the like comprising a frame carrying the stencil-sheet, a bed on which the paper to receive the impression is laid, two pairs of links connecting the frame with the bed, the pairs being of unequal effective length in order to cause the one end of the frame to rise more rapidly and to a greater extent than the other and thereof, and of one or more springs arranged to control the movements of said links, as set forth.

701,410. SOUND-RECOR. WALTER L. SAGE, Geneva, Iowa. Filed Nov. 23, 1901. Serial No. 68,877. (No model.)

Claim.—1. In a sound-recorder, in combination, a casing, an axially-movable rotatable diaphragm therein, and a plurality of deflectable arms

secured at one end to the casing and frictionally engaging the diaphragm and inclined in the direction of rotation thereof.

2. In a sound-recorder, in combination, a casing, a longitudinally-movable rotatable diaphragm therein, and a plurality of elastic fibers secured at one end to the casing and frictionally engaging the diaphragm with their free end, the said fibers being inclined in the direction of rotation of the diaphragm.

3. In a sound-recorder, in combination, a casing, a headed pin located in the casing, a disk rotatably mounted on and movable longitudinally as to the pin, and a plurality of elastic fibers secured in the casing and frictionally engaging the rear face of the diaphragm, the said fibers being inclined in the direction of rotation of the diaphragm.

4. In a sound-recorder, in combination, a casing, a rotating disk the rear face of which is roughened, a headed pin fixed in the back of and extending perpendicularly into the casing, a disk rotatably mounted on and movable longitudinally as to the pin, a plurality of elastic fibers secured at one end to the back of the casing and bearing with their free end against the back of the disk, the said fibers being inclined in the direction of rotation of the disk.

701,411. LASTING-MACHINE. STEPHEN SNOW, Everett, Mass., assignor to Portland Machinery Company, Portland, Me., and New York, N. Y. Filed May 7, 1900. Serial No. 68,887. (No model.)

Claim.—1. In a lasting-machine, a two-wiper, and means to move the same when in contact with the upper on the top of the last back of the toe and thereof forwardly toward and to the toe end of the last, said wiper moving in the arc of a circle located between the toe and heel of the last, and a toe-rest movable in the direction of the length of the last during the operation of the two-wiper, said toe-rest contacting with the upper on the top of the last back of the toe and thereof.

2. In a lasting-machine, a pivotally-mounted two-wiper, a two-wiper actuator to move the wiper longitudinally of the last and turn the same that its upper edge may contact with the upper lying on the top of the last and sliding over said upper stretch the same and fit it to the last, and a toe-rest connected with the said two-wiper actuator contacting with the upper on the top of the last at a point back of the toe and of the last and toe-wiper and movable longitudinally of the length of the last with and during the operation of the two-wiper.

3. In a lasting-machine, a two-wiper actuator, a two-wiper carrier pivoted thereto at its ends, and a connected two-wiper, combined with a toe-rest movable longitudinally of the length of the last during the operation of the two-wiper, said toe-rest contacting with the upper on the top of the last between the end of the last and the pivotal point of the two-wiper carrier.

4. In a lasting-machine, a two-wiper having its edge adapted to meet the upper on the top of the last back of the toe end of the last, and a toe-rest to contact with the upper on the last as the two-wiper completes its operative stroke and means to move the toe-rest and two-wiper longitudinally of the last and to turn the two-wiper when stretching and fitting the upper to the last.

5. In a lasting-machine, a two-wiper actuator, a two-wiper carrier pivoted thereto at its ends and a connected two-wiper, combined with a toe-rest supported on the two-wiper carrier, means to adjust the toe-rest with relation to the two-wiper to cause the toe-rest to contact with the upper on the top of the last and determine the position of the upper edge of the two-wiper when stretching the toe of the last.

6. In a lasting-machine, a grooved spindle, means carried thereby to jack and support a last, a spring to sustain said spindle, a movable carrier comprising a plunger and a bar having a guide-pin, a spring to move said carrier that the guide-pin may enter the groove of said spindle, said pin insuring the movement of the spindle in a vertical line, the withdrawal of said pin in opposition to said spring permitting the spindle to be rotated.

7. In a lasting-machine, a two-wiper actuator, a two-wiper, a two-wiper carrier pivotally mounted on said actuator at its ends, said carrier occupying normally a position between the toe and heel end of the last, a rod connected with said two-wiper carrier between its ends, and means to move said rod in the direction of its length to thereby cause the upper

end of the too-wiper to meet the upper on the last, and a too-rest connected with said rod.

8. In a lusting-machine, a too-wiper actuator, a too-wiper, a too-wiper carrier pivotally mounted on said actuator at its ends, said pivots occupying normally a position between the too and heel end of the last, a rod connected with said too-wiper carrier between its ends, and means to move said rod in the direction of its length to thereby cause the upper end of the too-wiper to meet the upper on the last and a too-rest connected with said rod, and means to adjust said too-rest vertically to thereby adapt it to the thickness of the last back of the end of the too.

701,412. LASTING-MACHINE. BREWSTER BROW, Everett, Mass. Assignor to Portland Machinery Company, Charleston, W. Va., and New York, N. Y. Filed June 25, 1900. Serial No. 21,397. (No Model.)

Claim.—1. In a lasting-machine, a pair of plate-carriers, two crimping-plates one for each carrier, said crimping-plates varying one from the other in the curvature of their crimping edges, and means for connecting said plates detachably with said carriers that they may be disengaged from one carrier, overturned, and transposed to the other carrier to enable right and left feet shoes to be lasted.

2. In a lasting-machine, a pair of plate-carriers, combined with crimping-plates detachably mounted in said carriers and having each a concave edge, said crimping-plates differing one from the other in the curvature of their crimping edges, each plate being capable of being detached, transposed to the other carrier, and, inverted to provide for right or left shoe lasting.

3. In a lasting-machine, a plate-carrier slotted at one end, a plate connected at one edge and notched and inserted in the slot of the plate-carrier, said notch engaging a projection of said carrier, and means acting upon said plate to lock it in the carrier.

4. In a lasting-machine, a plate-carrier slotted at one end, a plate connected at one edge and notched and inserted in the slot of the plate-carrier, said notch engaging a projection of said carrier, combined with a spring-controlled latch to engage and effect the retention of the plate in the carrier.

5. In a lasting-machine, crimping-plate carrier, attached crimping-plates, a main slide, a lever, and connections between said slide and said carrier to move the same; an intermediate slide, a clamp mounted thereon, a coupling adapted to be interposed between said two slides, it occupying its operative position when the two slides are moved to seat the clamp upon the upper, and means to thereafter move said coupling into its inoperative position to release it from said main slide that the plate-carrier and their crimping-plates may be further moved to lay the upper over the lower sole on the last.

6. In a lasting-machine, crimping-plate carrier, attached crimping-plates, a main slide, a lever, and connections between said slide and said carrier to move the same; an intermediate slide, a clamp mounted there-

on, a coupling adapted to be interposed between said two slides, it occupying its operative position when the two slides are moved to seat the clamp upon the upper, means to thereafter move said coupling in its inoperative position that the plate-carrier and their crimping-plates may be moved to lay the upper over the lower sole on the last, and a device under the control of said coupling to lock said intermediate slide in position, to maintain the clamp against the upper on the last holding the plate-carrier from lasting movement.

7. In a lasting-machine, a slide, a connected clamp, a spring-pressed notched block over which said slide is movable, a tooth on said slide to engage a notch of said block, and means to move said block that it may engage the tooth of the slide, or be made to rotate from said tooth as aid for the purpose set forth.

8. In a lasting-machine, a flexible clamp to embrace the end of the last, means to contain the ends of the clamp, and clamp-containing means intermediate the ends of said clamp and independent of the means for containing the ends of the clamp, said clamp being connected detachably with said intermediate clamp-containing means.

9. In a lasting-machine, a flexible clamp having attached to it between its ends a clotted plate, combined with a sliding clamp-containing device having slots engaged loosely with said plate to contain the central portion of the clamp detachably.

10. In a lasting-machine, crimping-plates, carriers for said plates, a slide operatively connected with said carriers, an intermediate slide, a clamp to embrace the end of the last, an overcar mounted on said intermediate slide, links connected at one end with said overcar and at their other ends with said clamp, means to move the slide connected with said carriers, a coupling to couple the said slides together that they may be moved together until said clamp embraces the upper on the end of the last, and means to then move the coupling to release the slide carrying the clamp while the slide moving the crimping-plates is further moved to meet the upper and lay it over upon the lower sole on the bottom of the last, and means to lock the clamp in its clamping position while the crimping-plates complete their operative movement.

11. In a lasting-machine, crimping-plates, carriers for said plates, a slide operatively connected with said carriers, an intermediate slide, a clamp to embrace the end of the last, an overcar mounted on said intermediate slide, links connected at one end with said overcar and at their other ends with said clamp, means to move the slide connected with said carriers, a coupling to couple the said slides together that they may be moved together until said clamp embraces the upper on the end of the last, and means to then move the coupling to release the slide carrying the clamp while the slide moving the crimping-plates is further moved to meet the upper and lay it over upon the lower sole on the bottom of the last, and means to lock the clamp in its clamping position while the crimping-plates complete their operative movement, and means to depress the locking device to unlock the slide for moving the clamp, that it may be moved backwardly after the completion of the action of the crimping-plates.

701,418. MACHINE FOR REDUCING WOOD TO FIBER. WILLIAM K. SUMNER, Syracuse, N. Y. Filed Jan. 24, 1902. Serial No. 91,311. (No Model.)

Claim.—1. A machine for reducing wood to fiber, comprising a rotary wood-carrier and a rotating cutter, an oscillatory support for one of the parts, and mechanism to rotate the carrier and simultaneously rock the support, a device to hold parts of said mechanism in engagement, and means actuated by the rocking support to automatically trip the device.

2. A machine for reducing wood to fiber, comprising a rotary wood-carrier and a rotating cutter, an oscillatory support for one of the parts and mechanism to rotate the carrier and simultaneously rock the support

at gradually-increasing speed, one of the members of said mechanism being detachable to prevent the variable speed movement of the rocking support for the purpose set forth.

3. A machine for reducing wood to fiber, comprising a rotary wood-carrier and a rocking frame carrying a rotating cutter, and mechanism connected and operating to rotate the carrier and to simultaneously rock the frame to move the cutter to the work.

4. A machine for reducing wood to fiber, comprising a rotary wood-carrier and a rocking frame carrying a rotating cutter, a screw adapted to rock the frame, and driving mechanism connected and operating to rotate the carrier and screw simultaneously.

5. A machine for reducing wood to fiber, comprising a rotary wood-carrier and a rocking frame carrying a rotating cutter, a screw adapted to rock the frame, and driving mechanism connected and operating to rotate the carrier and screw simultaneously at gradually-increasing rates of speed.

6. A machine for reducing wood to fiber, comprising a rotary wood-carrier and a rocking cutter-support, a driving member for the cutter, and a screw actuated by said member and connected to rock the cutter-support for the purpose specified.

7. A machine for reducing wood to fiber, comprising a rotary wood-carrier, an oscillatory frame, a rotating cutter mounted on the frame, a rotating driving member to rotate the carrier, and a screw actuated by said member and connected to oscillate the frame for the purpose set forth.

8. A machine for reducing wood to fiber, comprising a rotary wood-carrier, a movable cutter-support, a screw connected to move the support, a friction-disk, a frictional wheel engaged with and actuated by the disk, a worm driven by the wheel and connected to drive the screw, and connections whereby said frictional wheel is moved across the face of the disk to increase the speed of movement of the support as the wood is reduced for the purpose set forth.

9. A machine for reducing wood to fiber, comprising a rotary wood-carrier, a rotating friction-disk, a rotary friction member movable across the face of the disk and receiving its rotary motion from the disk, said member being connected to drive the carrier, a screw connected to and actuated by the said member, and means actuated by the screw and detachably connected to said member to move the same across the face of the disk, and a cutter connected with the carrier to reduce the wood to fiber.

10. In a machine for reducing wood to fiber, a rotating wood-carrier, a cutter, a rotating friction-disk, a screw, a rotary shaft having means fastened thereon and engaged with the disk and a worm on the shaft connected to drive the carrier and screw, said screw being connected to move said member across the face of the disk.

11. In a machine for reducing wood to fiber, a rotating wood-carrier, a rotating friction-disk, a screw, rotary means engaged with the disk and connected to drive the screw, a movable cutter-support connected to and actuated by the screw, and means detachably connected to said cutter-support to move the former across the face of the disk.

12. In a machine for reducing wood to fiber, a rotating wood-carrier, a rock-frame, a rotating cutter on the frame, a screw to rock the frame, a rotating friction-disk, a revolvable sliding member rotated by the disk and connected to drive the carrier and screw, and means connected to the rock-frame to slide said member across the disk.

13. In a machine for reducing wood to fiber, a rotating wood-carrier, a rock-frame, a rotating cutter on the frame, a screw to rock the frame, a rotating friction-disk, a revolvable sliding member rotated by the disk and connected to drive the carrier and screw, and means detachably connected to the rock-frame to slide said member across the disk.

14. In a machine for reducing wood to fiber, a rotary wood-carrier, a rocking cutter-support, means to rock said support, a driving member for said means having independent movement away from said means, a device holding said driving member in position, and additional means actuated by the rocking of the support to release the device.

15. In a machine for reducing wood to fiber, a rotating wood-carrier, a movable cutter-support, a screw engaging the support to move the cutter to the work, driving means for the screw, one of the two last-mentioned parts being movable toward and away from the other, a device holding the movable part in operative position, and additional means operated by the support to trip the device and thereby break the connection between the screw and its driving means.

16. In a machine for reducing wood to fiber, a rotating wood-carrier, a rocking frame, a rotating cutter on the frame, a screw for rocking the frame, a rotating friction-disk, and means driven by the disk and connected to rotate the carrier and screw, said means having an independent sliding movement across the disk, and connections between the rock-frame and said means to effect the sliding movement automatically.

17. In a machine for reducing wood to fiber, a rotating wood-carrier, a rocking frame, a rotating cutter on the frame, a screw for rocking the frame, a rotating friction-disk and means driven by the disk and con-

ected to rotate the carrier and screw, said means having an independent sliding movement across the disk, connections between the rock-frame and said means to effect the sliding movement automatically, and additional means actuated by the rock-frame to break the connection between the screw and its driving means.

18. In a machine for reducing wood to fiber, a rotating wood-carrier, a rocking frame, a rotating cutter on the frame, a screw for rocking the frame, a rotating friction-disk, and means driven by the disk and connected to rotate the carrier and screw, said means having an independent sliding movement across the disk, connections between the rock-frame and said means to effect the sliding movement automatically, said latter connections having a manually-movable member adapted to break the connection between the rock-frame and said means.

701,414. GAME APPARATUS. HARRY W. GRAMMEL, Chicago, Ill. Filed Dec. 15, 1900. Serial No. 20,957. (No Model.)

Claim.—1. A checkered game-board having a main part and wings and each of said wings having a "single corner" or man-space in each outer corner and a "double corner" or double man-space at each intersection of the wings, substantially as set forth.

2. A checkered game-board having a square common center the spaces in all corners of which are alike and having a wing extending from each of the different sides thereof, substantially as set forth.

3. A checkered game-board having a main part and wings and an odd number of man-spaces and blank spaces collectively in each row thereof extending longitudinally of the edge of the board in said main part and in each of said wings, including all of each space in each of said rows, substantially as set forth.

4. A checkered game-board having a main part and wings and a blank space at each corner of said main part and a man-space at each corner of each of said wings, substantially as set forth.

5. In a game apparatus differently-distinguished sets of movable men having different numerical values on different sides thereof and each of such men having one numeral on one side and a higher numeral on the other side, and the numerals on the men of each set corresponding with the numerals on the men of each other set, substantially as set forth.

6. In a game apparatus differently-distinguished sets of movable men having marks of different numerical value on different sides thereof and each mark of value on the different sides of each man also being of different numerical value, all substantially as set forth.

701,415. HIRE-YOKE CENTER. BREWSTER BROW, Orem, Utah. Filed Apr. 3, 1902. Serial No. 100,490. (No Model.)

Claim.—1. A hire-yoke center formed by carrying the end 7, of the material under and over the end 6, thereby forming openings 8 for

the yoke, and an opening 9 for the pole; the whole arranged whereby the greater the pull on the pole, the tighter the yoke is held.

2. A neck-yoke center formed by carrying the end 7 under and over the end 8, thereby forming openings 6 for the yoke, and an opening 9 for the pole.

3. A neck-yoke center formed of a strap, the free ends of which are secured to itself; the said strap being then twisted whereby the end 7 is carried under and over the end 8; thereby forming openings for the yoke and pole.

701,416. CAR SIDE BEARING. FRANKS & SUMNER, and AUGUSTUS TURNEY, Detroit, Mich. Filed Mar. 2, 1902. Serial No. 94,494. (No model.)

Claim.—1. In a car side bearing, the combination with the casing forming an endless roller-track, of an endless train of independent roller-trucks.

2. A car side bearing comprising in combination, a casing forming an endless roller-track, an endless train of independent roller-trucks, each roller-truck comprising a rigid frame with a roller mounted therein, substantially as described.

3. In a car side bearing, the combination with the casing forming an endless roller-track, of an endless train of independent roller-trucks, each roller-truck comprising a rigid frame, and a plurality of tapering rollers journaled therein.

4. In a car side bearing, the combination with the casing forming an endless roller-track, which guides the rollers, of an endless train of independent roller-trucks, each composed of a rigid frame and a pair of tapering rollers journaled in said frame.

5. In a car side bearing, the combination with the truck and body bolsters, of a side bearing consisting of a series of tapering rollers, a casing secured to one of the bolsters and forming an endless track for said rollers adapted to support a part of the rollers in traveling contact with the other bolster, and rigid truck-frames in which said rollers are journaled, said frame and rollers forming an endless train of roller-trucks.

6. In a car side bearing, the combination with the truck and body bolsters, of a side bearing consisting of a series of tapering rollers, a casing secured to one of the bolsters and forming an endless track in which said rollers are free to travel a portion of said travel being in contact with the other bolster, and rigid frames in which said rollers are journaled, said frames and rollers forming an endless train in which each frame and the rollers carrying the frame form an independent traveling unit.

7. In a car side bearing, the combination with the truck and body bolsters, of a side bearing consisting of an endless train of roller-trucks each composed of a rigid truck-frame and tapering rollers journaled in said frame, and a casing secured to one of the bolsters and forming an endless roller-track adapted to support a portion of the rollers in traveling contact with the other bolster, each truck-frame and its rollers forming a unit, guided in its travel in the casing independently of any other unit.

8. In a car side bearing, the combination with the truck and body bolsters, of a side bearing consisting of an endless train of roller-trucks each composed of a rigid truck-frame and tapering rollers journaled in said frame and a casing secured to one of the bolsters and forming an endless track for said roller-trucks, said casing provided with a core adapted to support a portion of the rollers in traveling contact with the other bolster and with projecting guide-flanges extending around the core at a distance apart equal to the bearing-face of the rollers and adapted to guide the rollers in their travel around the core.

9. In a car side bearing, the combination with the bolster and the casing secured thereto and forming an endless roller-track for guiding the rollers in their travel, of an endless train of independent roller-trucks, each composed of a rigid frame and two rollers removably journaled in said frame.

10. In a car side bearing, the combination with the bolster and the casing secured thereto and forming an endless roller-track for guiding the rollers, of an endless train of independent roller-trucks, each composed of a rigid frame formed of two side bars and a cross-bar centrally connecting

the side bars together and two rollers journaled in said side bars on opposite sides of the cross-bar.

11. In a car side bearing, the combination with the body-bolster and the casing secured thereto and forming an endless roller-track for guiding the rollers, of an endless train of independent roller-trucks, each composed of two rollers and a rigid frame composed of two side bars formed with open bearings in which the rollers are removably journaled and of a cross-bar uniting the side bars intermediate between the rollers.

12. In a car side bearing, the combination with the casing carried by the body-bolster and formed with a core around which the rollers are adapted to travel, of an endless train of independent roller-trucks, each composed of two tapering rollers formed with journals at their ends, and of a rigid frame formed of two side bars and a cross-bar, the side bars formed with open bearings to receive the journals of the rollers and provided with heads projecting over the ends of the journals.

13. In a car side bearing, the combination with the casing carried by the body-bolster and forming an endless roller-track, of an endless train of independent roller-trucks, each composed of two tapering rollers and of a rigid frame formed of two side bars provided with bearings in which the rollers are journaled, and of a cross-bar uniting the side bars between the rollers, the ends of the side bars being rounded off and projecting beyond the rollers.

14. The combination with the truck and body bolsters having a center bearing, of side bearings carried by the body-bolster each comprising a series of independent roller-trucks composed of a rigid frame and two taper rollers journaled in the frame, and a casing formed with a core around which the roller-trucks are adapted to travel in a path radial with the center bearing, said core provided with projecting parallel guide-flanges for the rollers extending around said core at a distance apart equal to the length of the bearing-face of the rollers.

15. The combination with the truck and body bolsters having a center bearing, of side bearings carried by the body-bolster, each comprising a series of independent roller-trucks and a casing formed with a core around which the roller-trucks are adapted to travel in a path radial with the center bearing, said core formed on its under side with a flat bearing-face formed of a steel plate secured to the core and with projecting flanges extending around the whole core for guiding the rollers in their travel around the core.

16. The combination with the truck and body bolsters having a center bearing, of side bearings carried by one of the bolsters, each comprising a series of independent roller-trucks composed of a rigid frame formed with side bars and of two rollers provided with journals engaging into bearings in the side bars and projecting beyond said bearings, a casing formed with an elongated core around which the trucks are adapted to travel, said core flat upon its upper and lower sides and with rounded ends projecting guide-flanges upon said core adapted to guide the rollers in their path around the core and retaining-flanges for the rollers projecting inwardly from the sides of the casing, said retaining-flanges adapted to form bearings for the projecting ends of the journals of the rollers in their travel around the rounded portions of the core.

17. The combination with the truck and body bolsters having a center bearing, of side bearings carried by one of the bolsters each comprising a series of independent roller-trucks D and a casing C formed with an elongated core G, the upper and lower sides of which form bearings for the rollers in the travel of the trucks around the core, guide-flanges A extending around the core, and the retaining and bearing flanges B projecting inwardly from the sides of the casing and stepped off at the top of the casing, said casing being open on top for the insertion and removal of the roller-trucks.

701,417. APPARATUS FOR SEPARATING CONDUCTORS FROM NON-CONDUCTORS. WALTER S. SWANN, Denver, Colo., and LOUIS I. BLAKE, Lawrence, Mass. Filed Oct. 22, 1901. Serial No. 93,098. (No model.)

Claim.—1. A conducting-belt, a charged conducting-plate mounted substantially parallel to said belt at the discharge end of the same, a dielectrically-charged conducting-plate below said end of said belt, an oppositely-charged metallic conducting-plate mounted near the discharge-end of said belt and means to collect the separated particles, and a feeding device comprising a hopper, a feed-board adjustably mounted with respect to said hopper, a series of non-conducting feed-cords mounted to move relatively to said feed-board and means to move said feed-cords with respect to said feed-board.

2. Apparatus for the electrical separation of particles comprising an electrically-charged portion and a feeding device adjacent said charged portion comprising a feed-board, means to adjust the slope of said feed-board, means to supply material to the upper end of said feed-board, a series of non-conducting cords mounted on said feed-board and means to move said cords relatively to said feed-board.

3. Apparatus for the electrical separation of particles comprising an

electrically-charged portion, and a feeding device arranged adjacent said charged portion comprising an inclined feed-board, a series of non-conducting feeding elements mounted on said feed-board and means to move said feeding elements relatively to said feed-board.

4. Apparatus for the electrical separation of particles comprising an electrically-charged portion, and a feeding device arranged adjacent said charged portion comprising an inclined feed-board, a series of non-conducting feeding-cords mounted on said feed-board and means to move said cords with respect to said feed-board.

5. In a feeding device, a hopper, a feed-board hinged to said hopper, means to adjust the inclination of said feed-board, a series of feed-cords mounted on said feed-board, said feed-cords passing through a series of guiding-clamps secured to said feed-board, each of said feed-cords being yieldably connected at one end to said feed-board, a feed-frame to which the other end of each of said feed-cords is connected, a cam, and a cam-follower engaging said cam secured to said feed-frame to reciprocate said feed-cords.

6. In a feeding device, an inclined feed-board, means to adjust the inclination of said feed-board, the discharge edge of said board being substantially horizontal, a series of horizontal feed-cords mounted on said feed-board and means to reciprocate said feed-cords with respect to said feed-board.

7. In a feeding device, an inclined feed-board, means to supply material to said feed-board, a series of feed-cords mounted on said feed-board and means to move said feed-cords longitudinally relatively to said feed-board to uniformly feed material down said feed-board.

8. In a feeding device, a horizontally-inclined feed-board and a series of relatively movable horizontal feed-cords.

9. In a feeding device, an adjustable inclined feed-board at substantially the angle of repose of the material fed over said board, a feed-cord mounted on said board and means to move said cord relatively to said board to feed material down said board.

10. In a feeding device, an inclined feed-board, means to adjust the inclination of said feed-board to substantially the angle of repose of the material fed over said board, a series of feed-cords mounted on said board, and means to move said cords relatively to said feed-board to feed said material down said feed-board.

11. In a feeding device, an inclined feed-board, means to adjust the inclination of said feed-board to substantially the angle of repose of the material fed down said board, elongated feeding elements mounted on said board to cooperate therewith, and means to longitudinally reciprocate said feeding elements to feed material down said board.

12. In a feeding device, an inclined feed-board at substantially the angle of repose of the material fed down said feed-board, elongated feeding elements mounted on said feed-board, and means to longitudinally move said elements to feed material down said feed-board.

13. In a feeding device, an inclined feed-board, the discharge edge of said feed-board being substantially horizontal, a horizontally-arranged elongated feeding element mounted on said feed-board substantially parallel to the discharge edge of the same, and means to longitudinally move said feeding element to feed material down said feed-board.

14. In a feeding device, an adjustable inclined feed-board having a horizontal discharge edge, a feed-cord mounted on said board substantially parallel to the discharge edge of the same, and means to move said cord relatively to said board to feed material down said board.

701,418. METHOD OF PRODUCING WEAVING-DIAGRAMS. JAN BUNDFELD, Vienna, Austria-Hungary, assignor to Société des Inventions Jan Bundfeld & Co., Vienna, Austria-Hungary, a Firm. Filed Mar. 12, 1902. Serial No. 93,501. (No specimens.)

Claim.—1. The method of producing diagrams for weaving multicolored fabrics, which consists in dividing in one direction the fields that represent stitches on a sensitive medium into three parts, producing monochrome dispositive from a suitable object, exposing each of the parts of the aforementioned fields to the action of light passed through one of said dispositive and a suitable screen arranged to indicate a weaving-stitch, substantially as described.

2. The method of producing diagrams for weaving multicolored fabrics, which consists in dividing the fields that represent stitches on a sensitive medium into three parts in the warp direction, producing monochrome dispositive and exposing said sensitive medium to the action of light passed through the dispositive, and a screen arranged to indicate a pattern-stitch, whereby each stitch in the warp direction will be represented by three colors, substantially as described.

3. The method of producing diagrams for weaving multicolored fabrics, which consists in dividing the fields that represent stitches on a sensitive medium into three parts in the warp direction, exposing each of said parts to the action of light passed through the dispositive and a screen arranged to indicate the particular weaving-stitch to be used, whereby each stitch in warp direction will be represented by the three primary colors, and indicating the web-binding by suitable means, substantially as described.

4. The method of producing diagrams for weaving multicolored fabrics, which consists in indicating the arrangement of the warp-threads, each of which is composed of three colors and arranging the indication of web-threads of white or black to bind and combine warp-threads and parts of warp-threads to produce high light and shadow, substantially as described.

5. The method of producing diagrams for weaving multicolored fabrics, which consists in indicating the arrangement of the threads in one direction, each of which is composed of three parts each of a different color and arranging the indication of black threads in the other direction to accentuate the shadows, and white threads also in the other direction to accentuate high lights, substantially as described.

701,419. CULTIVATOR. JAMES H. TAYLOR, Rome, Ga., assignor of one-half to JOHN H. VANDIVER, Rome, Ga. Filed June 22, 1901. Serial No. 93,578. (No model.)

Claim.—In a cultivator of the kind described the combination of a central draft-beam having a hook arranged upon its forward end, and handle-connections on the rear end thereof, cultivator-supporting arms pivotally connected at one end to the beam, brace-beams pivotally held to the free ends of said arms and having their opposite ends adjustably held to the central beam, downwardly-depending members held to the supporting-arms, each pair having their lower ends connected by a threaded bolt or shaft upon each of which is mounted a cultivator-disk, substantially as shown and described.

701,420. STEAM-ENGINE VALVE. ALFRED TAYLOR, Chicago, Ill. Filed Sept. 24, 1891. Serial No. 74,674. (No model.)

Claim.—1. In a valve for steam-engines, in combination, a slide-valve proper, having a steam-port and an exhaust-port; a piston exhaust-valve loosely mounted in said slide-valve and adapted to open and close the exhaust, said piston-valve being provided with a chamber at one of its ends; a duct in said valve for conveying live steam to said chamber; and a duct in said piston exhaust-valve adapted to be brought into coincidence with said first-mentioned duct by the movement of said piston-valve.

2. In a valve for steam-engines, in combination, a slide-valve proper, having steam-ports, an exhaust-port, and a longitudinal opening; a piston exhaust-valve free to move longitudinally in said opening and adapted to open and close the exhaust by its said movement, said piston-valve being provided with a chamber at one of its ends; a closure for one end of said longitudinal opening; a duct in said closure for conveying live steam to said chamber; and a duct in said piston exhaust-valve adapted to be brought into coincidence with the duct in said closure by the movement of said piston-valve.

3. In a valve for steam-engines, in combination, a slide-valve proper, having a steam-port and an exhaust-port; a piston exhaust-valve loosely mounted in said slide-valve and adapted to open and close the exhaust, said piston-valve being provided with a chamber at one of its ends; means of communication between said chamber and the boiler-pressure within the valve; means for opening and closing said communication; and a means of escape for the steam within said chamber.

4. In a valve for steam-engines, in combination, a slide-valve proper, having a steam-port and an exhaust-port; a piston exhaust-valve loosely mounted in said slide-valve and adapted to open and close the exhaust, said piston-valve being provided with a chamber at one of its ends; a duct in said valve for conveying live steam to said chamber; a duct in said piston exhaust-valve adapted to be brought into coincidence with said first-mentioned duct by the movement of said piston-valve; and a second duct in said piston-valve for the escape of the steam within said chamber.

5. In a valve for steam-engines, in combination, a slide-valve proper, having steam-ports, an exhaust-port, and a longitudinal opening; a piston exhaust-valve free to move longitudinally in said opening and adapted to

open and close the exhaust by its said movement, said piston-valve being provided with a chamber at one of its ends; a closure for one end of said longitudinal opening; a duct in said closure for conveying live steam to said chamber; a duct in said piston exhaust-valve adapted to be brought into coincidence with the duct in said closure by the movement of said piston-valve; and a second duct in said piston-valve for the escape of the steam within said chamber.

6. In a valve for steam-engines, in combination, a slide-valve proper, having a steam-port and an exhaust-port; a piston exhaust-valve loosely mounted in said slide-valve and adapted to open and close the exhaust, said piston-valve being provided with a chamber at one of its ends; means of communication between each of said chambers and the boiler-pressure within the valve; means for opening and closing said communication; and a means of communication between said chambers.

7. In a valve for steam-engines, in combination, a slide-valve proper, having a steam-port and an exhaust-port; a piston exhaust-valve loosely mounted in said slide-valve and adapted to open and close the exhaust, said piston-valve being provided with a chamber at one of its ends; a duct in said valve for each of the chambers, for conveying live steam to said chambers; a duct in each end of said piston-valve adapted to be brought into coincidence with one of said first-mentioned ducts by the movement of said piston-valve; and a means of communication between said chambers.

8. In a valve for steam-engines, in combination, a slide-valve proper, having steam-ports, an exhaust-port, and a longitudinal opening; a piston exhaust-valve free to move longitudinally in said opening and adapted to open and close the exhaust by its said movement, said piston-valve being provided with a chamber at one of its ends; a closure for each end of said longitudinal opening; a duct in each end of said piston-valve adapted to be brought into coincidence with the duct in one of said closures by the movement of said piston-valve; and a means of communication between said chambers.

9. In a valve for steam-engines, in combination, a slide-valve proper having steam-ports, an exhaust-port and a longitudinal opening; a piston exhaust-valve free to move longitudinally in said opening and adapted to open and close the exhaust by its said movement; a closure for each end of said longitudinal opening, said piston exhaust-valve being provided at its opposite ends with steam-chambers adapted to enable the entire movement of said exhaust-valve, and a connecting-duct between said chambers; and a projection extending from each of said closures for entering one of the said steam-chambers in the piston exhaust-valve.

10. In a valve for steam-engines, in combination, a slide-valve proper having steam-ports, an exhaust-port and a longitudinal opening; a piston exhaust-valve free to move longitudinally in said opening and adapted to open and close the exhaust by its said movement, said piston exhaust-valve being provided in its opposite ends with steam-chambers; means of communication between said steam-chambers and the boiler-pressure within said valve; closures for the ends of said longitudinal opening, each of said closures being provided with a guide-plate adapted to enter the adjacent steam-chamber in the piston exhaust-valve and a duct in said piston-valve communicating between said chambers.

11. In a valve for steam-engines, in combination, a slide-valve proper having two steam-ports, an exhaust-port and a longitudinal opening; a piston exhaust-valve of open form, free to move in said longitudinal opening and adapted to open and close the exhaust by its said movement, said piston exhaust-valve being provided at its opposite ends with projecting annular walls to form chambers to enable the entire movement of said exhaust-valve; a closure adapted to enter said chambers; and a duct in said piston-valve communicating between said chambers.

12. In a valve for steam-engines, in combination, a slide-valve proper having two steam-ports, an exhaust-port and a longitudinal opening, said longitudinal opening being counterbored on opposite sides of the exhaust-port and provided with means of communication with each of said steam-ports; a piston exhaust-valve free to move longitudinally in said opening and adapted to open and close the exhaust by its said movement, said piston exhaust-valve having at its opposite ends annular walls to form steam-chambers in each end of said piston-valve; means of communication between each of said chambers and the boiler-pressure in the steam-chest; closures for the opposite ends of said longitudinal opening, said closures being provided with guide-plates adapted to enter said steam-chambers in the piston exhaust-valve and a duct in said piston-valve communicating between said chambers.

13. In a valve for steam-engines, in combination, a slide-valve proper having steam-ports, an exhaust-port, and two longitudinal openings communicating with the exhaust-port; closures for the opposite ends of said openings; a piston exhaust-valve free to move longitudinally in each of said openings and adapted to open and close the exhaust by its said movement, each of said piston exhaust-valves being provided at its opposite ends with steam-chambers adapted to enable the entire movement of said exhaust-valves; a guide-plate extending from each of said closures

adapted to enter the chamber in one of said piston exhaust-valves; and a connecting-duct in each piston-valve for connecting the chambers in the opposite ends thereof.

701,431. ELECTRICAL HOOD OR REFLECTOR AND CLAMP FOR SAME. LEONARD L. THOMAS, New York, N. Y., assignor to the Van Tray Company, a Corporation of New Jersey. Filed Aug. 17, 1899. Serial No. 57,157. (No model.)

Claim.—1. The combination with an electric hood or reflector having a stem provided with an annular recess at its exterior, of a clamp comprising sections adjustably held together and at their ends next the hood or reflector having claws entering the said annular recess.

2. The combination with an electric-light hood or the like, having a stem with an exterior annular recess, of a clamp comprising sections adjustably held together intermediate of their ends, said clamp at its outer end being adapted to engage supporting means and its end at the other end having claws hooking into the said annular recess of the stem.

3. The combination with an electric-light hood or the like having a stem with an exterior annular groove, of a support having clamping members with claws adapted to enter said groove loosely and permit the hood to rotate while preventing motion in any other direction.

4. The combination with an electric hood or reflector having a stem provided with a peripheral groove, and with a fixed rounded head, of clamping members held at opposite sides of said stem and head and resting thereagainst at their opposite ends, the ends of said members at the rounded head being curved to fit thereagainst and the opposite ends at the stem having inwardly-directed extensions entering said groove, and means for connecting said clamping members intermediate of said head and stem and forcing them together, substantially as set forth.

5. The combination with a fixed arm providing a rounded head, of an electric hood or reflector having a stem provided with a peripheral groove and a clamp suitably connecting said stem of the hood or reflector to the rounded head of the arm, said clamp having sections adjustably held together intermediate of their ends and at one end forming claws entering the groove of the said stem and at the other end forming opposite curved jaws grasping the rounded head, and lateral supports for clamping-wires carried upon said clamp-sections, substantially as set forth.

701,432. STEAM-GENERATOR. ALFRED THOMSON, Geneva, Ohio, assignor to the Western Automobile and Manufacturing Company, Geneva, Ohio, a Corporation of Ohio. Filed Sept. 18, 1891. Serial No. 74,685. (No model.)

Claim.—1. In a steam-generator, the combination of a tube bent up and down and then coiled and closely nested having a central space, a tubular spiral coil occupying this space and connected at its upper end with the outlet end of the tube first mentioned, a tubular coil located below the taken heretofore mentioned and connected with the lower end of said tubular spiral coil, and a tubular coil located above the other tubes and connected with the outlet end of the lower coil, and a casing which incloses said tubular system, substantially as specified.

2. In a steam-generator, the combination of a tube bent up and down and then coiled and closely nested around a central space, the long reaches of said tube comprising a substantially vertical position, a tubular spiral coil C, of larger diameter than the tube first mentioned, occupying said central space and connected at its upper end with the outlet end of said tube B, a flat tubular coil D located below the other tubes and connected with the lower end of said spiral coil, the tube-coils C and D being of larger diameter than the tube B, and a flat coil located above the other pipes referred to of larger diameter and connected with the outlet end of

the lower flat coil D, and a casing inclosing said pipe system, substantially as specified.

701,433. ELECTRIC-ARC LAMP. GEORGE S. THOMAS, New York, N. Y., assignor to Westinghouse Electric & Manufacturing Company, a Corporation of Pennsylvania. Filed Aug. 18, 1891. Serial No. 74,686. (No model.)

Claim.—1. In an arc-lamp, a pair of carbons, a magnet in series therewith, a longitudinally-movable carbon-carrier controlled by the said magnet, and means for moving one of the carbons within the carrier at a faster rate than the carrier moves.

2. In an arc-lamp, a pair of carbons, a magnet in series therewith, a movable core for the said magnet, one of the carbons being mounted within the said core, and positive means for moving the said carbon in the same direction as the core but at a more rapid rate.

3. In an arc-lamp, a pair of carbons, a magnet in series therewith, a core for the said magnet, one of the carbons being in line with said core and adapted to move therewith, and means for advancing the said carbon faster than the core.

4. In an arc-lamp, a pair of carbons, a magnet in series therewith and located above the carbons, a core for the said magnet connected with

the upper carbon in line therewith, and means for moving the upper carbon faster than the core, whereby, when the core drops by reason of the partial demagnetization of the magnet, the feeding of the carbon will be accomplished positively and with great rapidity.

5. In an arc-lamp, a pair of carbons, a magnet in series therewith, a core for the said magnet, and a bracket on the said core in combination with feeding mechanism mounted on the said bracket, and means for bringing the feeding mechanism into operation when the core drops.

6. In an arc-lamp, a pair of carbons, a magnet in series therewith, a core for the said magnet in line with the carbons, feeding mechanism mounted on the core, and means brought into operation by the dropping of the core for actuating the said feeding mechanism.

7. In an arc-lamp, a pair of carbons, a magnet in series therewith, a core for the said magnet, and a carbon connected with the said core, in combination with a bracket mounted on the core, a toothed wheel engaging with the carbon, a pawl and ratchet for operating the toothed wheel, and means for bringing the pawl and ratchet into operation when the core drops.

8. In an arc-lamp, a pair of carbons, a magnet in series therewith, a core for the said magnet, one of the carbons being connected with the said core and partaking of its motion, in combination with a spring pressing against one side of the carbon, a toothed wheel pressing against the opposite side thereof, and means for actuating the toothed wheel, such means being brought into operation by the dropping of the core.

9. In an arc-lamp, a pair of carbons one of which is movable, a carrier for the movable carbon, a positive feeding mechanism for the carbon mounted on the said carrier, and means brought into operation by the dropping of the carbon for actuating the feeding mechanism.

10. In an arc-lamp, a movable carbon, a carrier therefor, a feeding mechanism mounted on the carrier, the carbon being adapted to move with the carrier in one direction and to be moved in the other direction both by the action of the carrier and that of the positive feeding mechanism.

701,424. CONVERTIBLE MACHINE TOOL. THOMAS F. TINEY, Alpena, Mich. Filed Aug. 28, 1901. Serial No. 73,568. (No model.)

Claim.—1. A convertible machine tool comprising an arvil-base adapted to support alternatively, a detachable arvil-top having at its inner end a chamber to admit the point of a drill-bit or a back-center attachment for lath-work, a movable main jaw, a horizontal shaft mounted in said movable jaw and constructed and arranged to carry interchangeable bit and grinding-wheel chucks or to form a lath-spindle, and connections between said arvil-base and movable jaw including a horizontal feed-screw.

2. A convertible machine tool comprising a chambered arvil-base having an open-topped chamber overhanging at its inner end by a ledge and constructed and arranged to support, alternatively, a detachable arvil-top or a back-center attachment for lath-work, constructed in common with a feed-rod to interlock with said ledge, a movable main jaw, a horizontal shaft which is mounted in said movable jaw and is adapted to carry in-

terchangeable bit and grinding-wheel chucks or to form a lath-spindle, connections between said arvil-base and movable jaw including a horizontal feed-screw, a short screw above and parallel with said feed-screw whereby said arvil-top or said back-center attachment is fastened in place, and mechanism for driving said shaft at different speeds including a detachable hand-crank applied directly to said shaft, a vertically-adjustable end-shaft supported by said movable main jaw parallel with the shaft first named, and high-speed sprocket-gearing one wheel and one chain of which are detachable together with a crank-handle for each detachable wheel, each gearing as a whole serving to transmit rotary motion from each detachable crank-handle to the shaft first named and to the bit or grinding-wheel carried thereby, substantially as hereinbefore specified.

701,425. EDGE-FINISHING MACHINE. THAXTER E. TRIPP, Lynn, Mass., administrator of Seth D. Tripp, deceased, assigner, by mesne assignments, to said Thaxter E. Tripp. Filed May 28, 1902. Serial No. 681,982. (No model.)

Claim.—1. In an edge-finishing machine, the combination of a vibratory frame, a tool-holder carried by it bearing one or more tools, a tool-operating device for oscillating the tool as the frame bearing it vibrates, and means for moving said tool-operating device into and out of operative position, substantially as described.

2. In an edge-finishing machine, the combination of a vibratory frame, a tool-holder carried by it bearing one or more tools, and a pivoted arm engaging said tool-holder which causes the tool to oscillate as the frame bearing it vibrates, substantially as described.

3. In an edge-finishing machine, the combination of a vibratory frame, a tool-holder carried by it bearing one or more tools, a pivoted arm engaging said tool-holder which causes the tool to oscillate as the frame bearing it vibrates, and means for moving said arm into and out of engagement with said tool-holder, substantially as described.

4. In an edge-finishing machine, the combination of a vibratory frame, a tool-holder pivotally supported thereon, a pivoted arm for engaging said tool-holder which causes it to oscillate as the frame bearing it vibrates, and means for moving said arm out of engagement with said tool-holder, substantially as described.

5. In an edge-finishing machine, the combination of a vibratory frame, a rising and falling tool-holder carried by it bearing one or more tools, a spring-pressed arm engaging said tool-holder, which causes the tool to oscillate as the frame bearing it vibrates, and which yieldingly holds down said tool-holder, substantially as described.

6. In an edge-finishing machine, the combination of a vibratory frame, a rising and falling tool-holder carried by it bearing one or more tools, a spring-pressed arm engaging said tool-holder, which causes the tool to oscillate as the frame bearing it vibrates, and which yieldingly holds down said tool-holder, and means for moving said arm to disengage the tool-holder, substantially as described.

7. In an edge-finishing machine, a vibratory frame, a tool-holder carried by it bearing one or more tools, a spring for holding said tool-holder in a predetermined position relative to the frame bearing it, yet permitting it to be moved bodily forward by the work, and means for oscillating said tool-holder as the frame bearing it vibrates, substantially as described.

8. In an edge-finishing machine, a vibratory and rearwardly-moving frame, a tool-holder carried by it bearing one or more tools, a spring for

holding said tool-holder in a predetermined position relative to the frame bearing it, yet permitting it to be moved bodily forward by the work, and means for oscillating said tool-holder as the frame bearing it vibrates, substantially as described.

9. In an edge-finishing machine, a vibratory and rearwardly-moving frame, a tool-holder carried by it bearing one or more tools, means for oscillating said tool-holder as the frame bearing it vibrates, and a spring-pressed bar against which the lower end of said frame bears which serves as a yielding abutment thereby making its rearward movement, substantially as described.

10. In an edge-finishing machine, the combination of a vibratory frame, a tool-holder carried by it bearing one or more tools, a pivoted arm engaging said tool-holder which causes the tool to oscillate as the frame bearing it vibrates, and means for moving said arm into and out of engagement with said tool-holder and a spring upon which said arm bears as it engages the tool-holder, substantially as described.

11. In an edge-finishing machine, the rotating shaft of a having a crank-pipe projecting from it, a cylindrical bushing having an eccentrically-disposed hole adapted to receive said crank-pin, means for holding said cylindrical bushing in any position of rotary adjustment on said crank-pin, a vibratory frame having an independently-movable bar in said bushing, and a tool-holder operated by said vibratory frame bearing one or more tools, substantially as described.

12. In an edge-finishing machine, a vibratory frame, a tool-holder having a number of tools and having a corresponding number of engaging portions, combined with a tool-operating device and means for operating it to engage any one of said engaging portions, to thereby hold the tool-holder with any one of its tools in operative position, and to also operate said tool as the frame bearing it vibrates, substantially as described.

13. In an edge-finishing machine, a vibratory frame, a tool-holder having a number of tools and a number of recesses, combined with a pivoted spring-pressed arm and means for operating it to engage any one of said recesses to thereby hold the tool-holder with one of its tools in operative position and to also operate said tool as the frame bearing it vibrates, substantially as described.

14. In an edge-finishing machine, a vibratory frame, a tool-holder having a number of tools and having a corresponding number of engaging portions, combined with a movable tool-operating device engaging any one of said engaging portions to thereby hold the tool-holder with any one of its tools in operative position, and to also operate said tool as the frame bearing it vibrates, substantially as described.

15. In an edge-finishing machine, a vibratory frame, a tool-holder having a number of tools and having a corresponding number of engaging portions, combined with a pivoted spring-pressed arm engaging any one of said engaging portions to thereby hold the tool-holder with any one of its tools in operative position and to also operate said tool as the frame bearing it vibrates, substantially as described.

701,426. FENCIBLE-TOOL. CHARLES L. TUTTLE, Rochester, N. Y., assigner of one-half to Henry B. Whipple, Rochester, N. Y. Filed Feb. 12, 1902. Serial No. 68,746. (No model.)

Claim.—1. A fence-post comprising a metallic skeleton and a body of concrete or cement covering the walls or sides of the skeleton, the lat-

ter being conical or tapering, with its upper end closed and the lower end open, substantially as shown and set forth.

2. A fence-post comprising a metallic skeleton and a body of concrete or cement covering the walls or sides of the skeleton, the latter being longitudinally fluted, with parts projecting from the hollow or concave sides of the flutes, substantially as shown and described.

3. A fence-post comprising a metallic tube or skeleton longitudinally fluted with projections extending from the concave sides of said flutes and a body of concrete or cement covering the walls or sides of the tube or skeleton, and means for holding the horizontal members of a fence, substantially as shown and set forth.

4. A fence-post comprising a metallic tube or skeleton longitudinally fluted with projections extending from the concave sides of said flutes and a body of concrete or cement covering the walls or sides of the tube or skeleton, and holders for parts of the fence projecting from the post and passing through the metal skeleton or tube, substantially as shown.

701,427. RED DYE AND PROCESS OF MAKING SAME. JULIUS VILLER, Montpellier, France. Filed Oct. 5, 1901. Serial No. 71,088. (Specimens.)

Claim.—1. The herein-described process of producing a coloring-matter which dyes red, said process consisting in heating dialkyltinmetaphosphoric acid in acetic liquor with an oxidizing agent and alcohol.

2. The herein-described process of producing a coloring-matter which dyes red, said process consisting in heating dialkyltinmetaphosphoric acid in acetic liquor with an oxidizing agent and alcohol.

3. A new coloring-matter obtained by heating dialkyltinmetaphosphoric acid in acetic liquor with an oxidizing agent, sodium acetate and alcohol, appearing in the form of minute whitish crystals slightly soluble in cold water but more soluble in hot water with orange-yellow fluorescence and dyeing red.

701,428. AUTOMATIC VENT-VALVE. LAWRENCE J. WALKER, New York, N. Y., assigner of one-fourth to Edward J. Sullivan, Boston, Mass. Filed June 28, 1901. Serial No. 68,598. (No model.)

Claim.—1. As an article of manufacture, an automatic vent-valve, comprising a casing having upper and lower sections provided with spindles and normally secured together by a lip-joint, the upper section being provided with an annular valve-seat and the lower section being provided with a valve-plate, a cylindrical float mounted centrally inside of the casing and provided with a flat disk secured upon the upper surface of the said cylindrical member for the purpose of engaging said annular valve-seat, said cylindrical member being also provided with a guide-rod extending through said spindles.

2. As an article of manufacture, an automatic vent-valve, comprising a casing having upper and lower sections provided with spindles and normally secured together by a lip-joint, the upper section being provided with an annular valve-seat, a valve-plate located at the bottom of the lower section, a cylindrical member having one of its ends covered with a flat disk for engaging said annular valve-seat, and a guide-rod located centrally through both said cylindrical member and said disk.

701,429. PROCESS OF HARDENING COPPER. GRANT L. WALKER and FRANKLIN W. KIRBY, Rochester, N. Y. Filed Nov. 2, 1902. Serial No. 88,504. (No specimens.)

Claim.—The herein-described method of hardening copper, which consists in placing shanklets and charcoal in a crucible, supplying to the crucible a superheated mass of copper, and then applying heat to the crucible, causing thereby combustion of the charcoal and generation of carbonic acid gas which passes upward through the copper, carrying off any contained moisture in the metal and at the same time preventing oxidation thereof, whereby upon fusion of the metal, the copper, owing to its superior specific gravity, will intimately combine with the shanklets producing thereby a hardened copper alloy.

701,430. CURRENT-METER. WILLIAM L. WALKER, Fort Worth, Tex., assigner of one-half to Samuel W. Smith, Fort Worth, Tex., and Earl E. Brockway, Washington, D. C. Filed July 1, 1901. Serial No. 68,684. (No model.)

June 3, 1903.

Claim.—1. In a current-meter, the combination of an endless cable; means for supporting said cable with the lower stretch thereof in a submerged position; a series of paddles mounted intermediate the upper and lower stretches of the cable; and means for bringing the paddles successively into operative relation with the lower stretch of the cable.

2. In a current-meter, the combination of an endless cable; means for supporting the same with the lower stretch thereof in a submerged position; a series of paddles mounted intermediate the upper and lower stretches of said cable; means for bringing the paddles successively into operative relation with the lower stretch of the cable; and means for disengaging the paddles successively as they near the end of the lower stretch of the cable and passing them upwardly and back toward the forward end of the lower stretch.

3. In a current-meter, the combination of an endless cable; means for supporting the lower stretch thereof in a submerged position; a series of paddles; means for successively bringing the paddles into operation with the lower stretch of the cable; means for releasing said paddles as they near the end of the lower stretch; and means for elevating said paddles and carrying them forward toward the forward end of the lower stretch of the cable, substantially as described.

4. In a current-meter, the combination of an endless cable; means for supporting the same with the lower stretch thereof in a submerged position; a series of paddles mounted intermediate the upper and lower stretches of said cable; means for traversing said paddles in a circular path intermediate the upper and lower stretches of the cable; means for successively bringing said paddles into operative engagement with the lower stretch of the cable; means for disengaging said paddles therefrom as they near the end of said stretch; and means for bringing the paddles into operative relation with the upper stretch of the cable and moving them therewith toward the forward end of the meter.

5. In a current-meter, the combination of a pair of endless cables; means for supporting the same with the lower stretches thereof in a submerged position; a pair of paddle-carrying chains between the upper and lower stretches of the endless cables; a series of paddles pivotally connected to said paddle-carrying chains; means for causing the successive engagement of the paddles with the lower stretches of the cables; means for disengaging the paddles from said lower stretches; means for elevating said paddles and causing them to engage with the upper stretches of the cables; and means for disengaging the paddles from said upper stretches and carrying them around into proper position for engagement with the lower stretches.

6. In a current-meter, the combination of a pair of endless cables; means for supporting the same with their lower stretches in a submerged position; a pair of paddle-carrying chains mounted intermediate the upper and lower stretches of said cables; a series of paddles pivotally connected to said chains; means for causing said paddles to look there to the upper and lower stretches of the cables; and mechanism for releasing and locking said means and carrying the paddles from one stretch to the other stretch of the cables.

7. In a current-meter, the combination of a pair of endless cables; means for supporting the same with their lower stretches in a submerged position; a series of buttons or stops attached to said cables; a pair of paddle-carrying chains mounted between the upper and lower stretches

of said cables; paddles carried by said chains; levers pivotally connected to the paddles; slides mounted upon the paddles and each connected with a lever; a fork carried at the outer end of each slide; and means for operating the levers and causing the forks to engage the cables and the buttons carried thereby, substantially as described.

8. In a current-meter, the combination of a pair of endless cables; means for supporting the same with their lower stretches in a submerged position; a series of buttons or stops attached to said cables; a pair of paddle-carrying chains mounted between the upper and lower stretches of said cables; paddles carried by said chains; levers pivotally connected to the paddles; slides mounted upon the paddles and each connected with a lever; a fork carried at the outer end of each slide; means for operating the levers and causing the forks to engage the cables and the buttons carried thereby; and means for withdrawing the forked ends from engagement with the cables as the paddles pass from one stretch to the other of the cables.

9. In a current-meter, the combination of a pair of endless cables; means for supporting the same with their lower stretches in a submerged position; a series of buttons or stops attached to said cables; a pair of paddle-carrying chains mounted between the upper and lower stretches of said cables; paddles carried by said chains; levers pivotally connected to the paddles; slides mounted upon the paddles and each connected with a lever; a fork carried at the outer end of each slide; means for operating the levers and causing the forks to engage the cables and the buttons carried thereby; means for withdrawing the forked ends from engagement with the cables as the paddles pass from one stretch to the other of the cables; and means for holding the paddles in their proper position as they pass from one stretch to the other of the cables.

10. In a current-meter, the combination of a pair of endless cables; means for maintaining the lower stretches thereof in a submerged position; a pair of paddle-carrying chains mounted intermediate the upper and lower stretches of the cables; a series of paddles pivotally connected to said chains; pivoted levers carried by the paddles; means connected to said levers for engaging the stretches of the cables; a track located beneath the upper stretches of the cables to hold the outer ends of the levers in a raised position; runways *a, p* mounted in line with said track and serving to control the outer ends of the levers; and means for holding the paddles in their proper position as they pass around in line with said runways.

11. In a current-meter, the combination of a pair of endless cables; means for holding the lower stretches thereof in a submerged position; a pair of paddle-carrying chains mounted intermediate the upper and lower stretches of said cables; a series of paddles pivotally connected to said chains; levers pivotally connected to the paddles; means connected to said levers for engaging the stretches of the cables; tracks located below the upper stretches of said cables; runways *a, p* in line with the ends of said tracks and arranged to control the outer ends of said levers as the paddles near the end of the upper and lower stretches respectively; and means for properly maintaining the paddles as they pass around through said runways.

12. In a current-meter, the combination of a pair of endless cables; means for maintaining said cables with their lower stretches in a submerged position; a pair of paddle-carrying chains mounted intermediate the upper and lower stretches of said cables; a series of paddles pivotally connected to said chains; means for connecting the paddles successively to the upper and lower stretches of the cables; means for withdrawing the connections intermediate said paddles and the cables as the paddles pass from one stretch to the other; arms extending out from the paddles; notched wheels designed to receive said arms; and endless cables passing about said wheels holding the arms in the notches as the paddles pass from one stretch of the cable to the other.

13. In a current-meter, the combination of a pair of endless cables; means for supporting the same with the lower stretch thereof in a submerged position; a pair of paddle-carrying chains mounted between the upper and lower stretches of the endless cables; a series of paddles pivotally connected to said paddle-carrying chains; means for causing the successive engagement of the paddles with the lower stretches of the cables; means for disengaging the paddles from the ends of said lower stretches; and connections intermediate the supports for the cables and the chains.

14. In a current-meter, the combination of a reliable support; a pair of shafts located one at each end thereof; a pair of wheels carried by each shaft; endless chains or cables passing about said shafts; a second pair of shafts mounted on the support intermediate the first pair of shafts; a pair of wheels carried by each of said second pair of shafts; endless chains passing about said wheels; a series of paddles pivotally connected to said chains; means for causing the paddles to successively engage the lower stretches of the cables; and a wheel *A'* carried by one of the intermediate shafts; a wheel *A* carried by the adjacent shaft of the outer pair; and a driving connection passing about said wheels.

15. In apparatus of the class described, a current-meter comprising

June 3, 1903.

U. S. PATENT OFFICE.

2163

a pair of cables, paddles mounted upon one of the cables and having detachable connections with the other cable, and connections between the cables for causing them to move in unison and maintain the paddles in fixed relation thereto while said paddles are connected in both cables.

701,481. DOOR-CHECK. JOHN WATTS, Akron, Ohio. Filed Apr. 2, 1898. Serial No. 161,178. (No model.)

Claim.—1. An improved door-check consisting of two metallic leaves, united at one end, and having a pivoted lever in the free end of one leaf with an eccentric flange to engage and bear on the face of the other leaf, substantially as shown and described.

2. An improved door-check consisting of two metallic leaves, united at one end and of which one has a corrugated flange, and the other having a pivoted lever in its free end with an eccentric corrugated flange to engage and bear on the corrugated flange of the opposite leaf, substantially as shown and described.

701,482. ICE-HEATER. RALPH L. WAIN, Baker City, Oreg., assignor of one-half to Thomas G. Burke, Baker City, Oreg. Filed Aug. 9, 1898. Serial No. 171,541. (No model.)

Claim.—The herein-described ice-heater consisting essentially of the cylinder, the piston made up of the approximately horizontal portion *f* joined to and extending outwardly from the lower end of the cylinder, and having the upwardly, outwardly and downwardly extending flange *f'* at its outer edge; said flange being disposed at right angle to the portion *f*, and the vertical skirt portion curved at its upper edge in the flange *f'* of portion *f* and depending from said portion *f* and having notches in its lower edge; said flange *f'* serving to connect the outer edge of the portion *f* and the upper edge of the skirt portion *g* and bend rigidly and strength to the base as a whole, the forked flange connected to the base portion *f*, and the piston movable in the cylinder.

701,483. ANASTYLENE-GAS GENERATOR. JOHN W. WAIN, Providence, R. I., assignor to The Universal Anastylene Company, Providence, R. I., a Corporation of Rhode Island. Filed May 2, 1891. Serial No. 81,405. (No model.)

Claim.—1. In an anastylene-gas generator, the combination of a water-tank; a carbide-holder located at the top of the water-tank; a gasometer, an interposed hollow water-tight connecting member uniting the water-tank with the tank of the gasometer, said member having an opening at the upper part into the water-tank and an opening at the lower part into the tank of the gasometer, a bent lever pivoted in proximity to said lower opening of said member and having one arm operated by the gasometer, the lever having its other arm extending upwardly through said connecting member, and means connected with the free end of said lever arm for opening said carbide-holder.

2. In an anastylene-gas generator, the combination of a water-tank, a carbide-holder located at the top of the water-tank, a gasometer, an interposed connecting member uniting the water-tank with the gasometer-tank, said member having an opening at the upper part into the water-tank and an opening at the lower part into the tank of the gasometer, a bent lever pivoted in proximity to said lower opening and having one arm extending upwardly in the gasometer, an inclined rod in the gas-

ometer arranged to engage said arm and thereby move the lever on the movement of the gasometer, the other arm of the bent lever extending upwardly through the connecting member, and a rod connecting the end of said lever arm with the carbide-holder.

3. In an anastylene-gas generator, the combination of a water-tank, a carbide-holder located at the top of the water-tank, a gasometer, an interposed connecting member uniting the water-tank with the gasometer-tank, said member having an opening at its upper part into the water-tank and an opening at its lower part into the tank of the gasometer, a gas-washing chamber located in the base of the gasometer, a pipe communicating with said connecting member just below the top of said water-tank and just above the normal water-line, said pipe communicating with the gas-washing chamber near its bottom, and an exterior outlet or overflow communicating with said gas-washing chamber for limiting the height of water in the latter.

4. In an anastylene-gas generator, the combination with the gasometer and gas-generating tank, B, C, respectively, and gas-washing chambers located below the tank B, of the interposed hollow water-tight connection H uniting said tanks and communicating therewith by means of suitable openings, the opening in tank C being at the normal water line or level, a gas-pipe *i* leading from the upper end of said connection H and discharging into the said gas-washing chamber and an exterior outlet overflow-vent communicating with said gas-washing chamber thus limiting the height of water in the latter, substantially as described.

5. In an anastylene-gas generator, the combination of a reliably-mounted carbide holder or reservoir having a tilted bottom member supporting the carbide, a reversible feed-wheel having its rim provided with projecting pins or fingers arranged to enter upwardly through and travel along said rim so as to discharge a quantity of the carbide from the holder, and means substantially as described for intermittently rotating the feed-wheel.

6. In an anastylene-gas generator, the combination of a reliable delivery crank-shaft or eccentric and the feed-wheel G, the latter having a reversible inner sleeve mounted on the crank portion of the shaft and a series of radially-movable fingers held in said sleeve and extending through the rim of the wheel, arranged whereby upon rotating the wheel the outer portion of the fingers will be successively and gradually projected beyond the rim and then retracted, substantially as described.

7. In an anastylene-gas generator, the combination of the reversibly-mounted carbide-feeding wheel G, provided with peripherally-arranged fingers and a ratchet or toothed member, a swinging arm carrying said dropping pins arranged to engage the said toothed member, a vertically-movable gasometer, and mechanism connected with said swinging arm and gasometer, whereby the latter is adapted to rotate the feed-wheel, substantially as described.

8. In an anastylene-gas generator, the combination with the carbide-holder and the feed-wheel, reversibly mounted below the throat of said holder, provided with a series of independent fingers or agitators, of a tilted base member for supporting the carbide and forming the bottom of the throat and at the same time also forming a shield for the upper portion of the wheel, in that the latter is not in direct contact with the carbide, and means actuated on rotation of the wheel for gradually passing said fingers upwardly through the shield portion of the base to engage

the cord and discharge it from the throat of the holder, substantially as described.

701,484. VEHICLE-TIRE. GEORGE A. WHEATLEY, Indianapolis, Ind., assignor to the G. & J. Tire Company, Indianapolis, Ind., a Corporation of Indiana. Filed Oct. 3, 1901. Serial No. 77,945. (No model.)

Claim.—1. The combination, in a vehicle-wheel, of a tire open on the under side and having ribs adjacent to the open portion, the inner surface opposite said ribs being inclined or tapered, an inner supporting-band formed to rest upon said inclined or tapered surface, and a channelled wheel rim or fully composed of two parts adapted to fit over the ribs on the tire, one part being adjustable toward and from the other, whereby the tire may be firmly grasped between the parts of the rim or fully and the inclined surface of the inner band, and also conveniently released therefrom.

2. The combination, in a vehicle-wheel, of a tire open on the under side and having smaller ribs adjacent to the open portion, a supporting-band adapted to be inserted within the tire just above the open portion, a channelled rim or fully divided into two parts one of which is movable toward and from the other, the movable part being carried by bolts or screws, and said bolts or screws, said several parts being constructed, arranged and operating substantially as shown and described.

701,485. BROWN-VIOLET SULFUR DYE AND PROCESS OF MAKING SAME. ARTHUR WEINBERG, Frankfurt-on-the-Main, Germany, assignor to Leopold Cassella & Co., Frankfurt-on-the-Main, Germany. Filed Jan. 6, 1901. Renewed Jan. 13, 1902. Serial No. 80,568. (No specimens.)

Claim.—1. The process of producing a brownish-violet dyestuff by heating arylsulfonates of the formula

(in which R stands for hydrogen, chlorine, a sulfide group or a carbonyl group) with alkaline sulfide and water substantially as described.

2. The coloring-matter produced as hereinbefore described which is a dark-violet or black powder, dissolving in concentrated sulfuric acid with a violet-black color being precipitated from this solution by addition of water, easily soluble in water in presence of alkaline sulfide, dyeing unmercerized cotton brownish-violet shades fast to washing, alkaline acids and light substantially as described.

701,486. WINDOW-SHADE-CORD CLAMP. EDWARD J. WELLS and JOHN F. YOUNG, Boston, Iowa. Filed Apr. 4, 1901. Serial No. 84,348. (No model.)

Claim.—1. A clamp for a window-shade-suspending cord comprising a fixed attaching-bracket having an eye for the loose reception of the cord, a clamping-plug slidably arranged in the eye and projecting from the same in opposite directions, and an exterior spring engaging the bracket and the plug and holding the latter normally in its engaging position, substantially as described.

2. A clamp for a window-shade-suspending cord, comprising a screw-

eye for the loose reception of the cord, a clamping-plug slidably mounted in the eye, and a spring bearing in opposite directions against the screw-eye and the plug to elastically yieldably hold the plug in its normal clamped position.

3. A clamp for a window-shade-suspending cord, comprising a bracket having an opening therein, a tubular plug slidably mounted in the opening and provided with a lateral opening, and a coiled spring embracing the plug and bearing in opposite directions against the same and the bracket.

4. A clamp for a window-shade-suspending cord, comprising a bracket having an opening therein, a tubular plug slidably mounted in the opening, and provided with a lateral perforation, and an upper external marginal flange, and a coiled spring embracing the plug and bearing in opposite directions against the bracket and the flange.

5. A clamp for a window-shade-suspending cord, comprising a screw-eye, a tubular plug slidably mounted therein, and having a lateral perforation formed in the lower portion and to cooperate with the screw-eye, and an upper external marginal flange, and a coiled spring embracing the plug, with its lower end resting upon the screw-eye and its upper end bearing upwardly against the flange of the plug.

6. A clamp for a window-shade-suspending cord, comprising an attaching-bracket having an opening therein, and a tubular clamping-plug slidably mounted in the opening and also provided with a lateral perforation, one wall of which is adapted to cooperate with the adjacent portion of the bracket to clamp the cord therebetween.

7. The combination with a window-shade-suspending cord, of a clamp therefor, comprising an attaching-bracket having an opening therein, and a spring-pressed tubular clamping-plug slidably mounted in the opening, and provided with a lateral perforation, the cord being passed into one end of the tubular plug and then outwardly through the lateral perforation therein, one wall of the perforation coacting with the adjacent portion of the bracket to clamp the cord therebetween, and the plug being yieldable to separate said wall and the bracket to release the cord.

701,487. BUTTER-HANDLE-BARREL. EDWARD F. WHEELER, Detroit, Mich., assignor to the Wheeler Manufacturing Company, Detroit, Mich., a Corporation. Filed May 27, 1901. Serial No. 82,182. (No model.)

Claim.—1. In a device for the purpose set forth, the combination with an oblong barrel adapted to be secured to the end of a handle-bar and having an interior channel extending longitudinally along its opposite ends and around its outer end; of a covering of two members curved together by through-stitches near their edges with their outer faces in contact and placed upon the core with the projecting margin of the same lying in said channel; and a socket-structure surrounding the lower open end of the core and the inner end of the covering and clamping these two parts together.

2. In a device for the purpose set forth, the combination of a core having a shoulder formed near and flaring away from one end thereof, a covering embracing said core and extending across said shoulder, and a socket-structure mounted upon the end of the core and upon the covering and having its edge turned inward and into direct contact with the covering so as to force the latter against said shoulder and lock itself and the covering to the core.

701,488. COMPRESSED TABLET. ROBERT H. WATTS, Jersey City, N. J., assignor to Schell & Company, New York, N. Y., a Corporation. Filed Feb. 19, 1902. Serial No. 80,590. (No specimens.)

Claim.—1. The method of making composite dry tablets or pills which consists in forming a layer of a dry powdered chemical, then forming a second layer in contact with the first of a dry powdered chemical capable of reaction with the first chemical and compressing the entire mass.

2. A composite pill or tablet consisting of two parts or sections of dry chemicals compressed together in contact the two sections with the other, said chemicals being adapted when wet to react and produce a desired drug.

3. A composite pill or tablet consisting of two layers of different chemicals compressed together in contact, said chemicals being adapted when wet to react and produce a desired drug.

4. In a composite pill or tablet consisting of dry chemicals which

tend when mixed and compressed together to suffer deterioration, a section of each of said chemicals combined with the other, said two sections being compressed together in contact, the one with the other.

5. A composite pill or tablet consisting of two parts or sections each composed of a separate dry chemical, said sections being compressed together in contact the one with the other, and said chemicals, when allowed to react not producing material quantities of gas.

701,489. HYDRAULIC RIVETING OR PUNCHING TOOL. CARL WIERTZ, Brooklyn, N. Y., assignor to Francis H. Stillman, Brooklyn, N. Y. Filed Mar. 11, 1901. Serial No. 80,690. (No model.)

Claim.—1. A hydraulic riveting or punching tool comprising the combination of: a ram; a jaw pivoted between its ends to the body of the tool and extending in front of the ram; devices on the ram and jaw that coact on the work on one side of the pivot-pin; and a removable block that fits between the jaw and body on the other side of the pivot-pin; substantially as described.

2. A hydraulic riveting or punching tool comprising the combination of: a body containing a fluid-reservoir; a hollow part on the body; a screw engaging with the hollow part and having an extension that passes into the reservoir; a ram whose axis is transverse to that of the reservoir and whose chamber is connected with the reservoir; a jaw pivoted to the body and extending in front of the ram; devices on the jaw and ram that coact on the work; and means to prevent the jaw from turning under the action of the ram; substantially as described.

3. A hydraulic riveting or punching tool comprising the combination of: a body containing a fluid-reservoir; a hollow part on the body; a screw engaging with the hollow part and having an extension that passes into the reservoir; a ram whose axis is transverse to that of the reservoir and whose chamber is connected with the reservoir; a jaw pivoted between its ends to the body and extending in front of the ram; devices on the ram and jaw that coact on the work on one side of the pivot-pin; and a removable block that fits between the jaw and body on the other side of the pivot-pin; substantially as described.

701,440. TELESCOPING VALVE. THOMAS A. WHEATLEY, Cincinnati, Ohio, assignor to Walter W. Warwick and Frank E. Warwick, Cincinnati, Ohio. Filed May 26, 1901. Serial No. 81,914. (No model.)

Claim.—1. A lock attached to the ends of the sections of a telescope-valve and inwardly projected therefrom, consisting of a head and socket formed to telescope and to interlock against lateral strain, detents in the socket, and locking means housed in said head adapted to be engaged into said detents, substantially as specified.

2. A lock attached to the ends of the sections of a telescope-valve inwardly projected therefrom, consisting of a telescoping head and socket formed to interlock transversely to the plane of telescopic action, detents in the socket, locking means housed in the head adapted to be engaged into said detents to interlock the sections in the plane of telescopic action, and means for releasing said locking means from the detents, substantially as specified.

3. A lock attached to the ends of the sections of a telescope-valve inwardly projected therefrom, consisting of a dovetailed telescoping head

and socket, detents in the socket, and locking means housed in the head adapted to be engaged into said detents, substantially as specified.

4. A lock attached to the ends of the sections of a telescope-valve, consisting of a socket attached to the under section, a head attached to the top section, the said head telescoping within the socket, the said head and socket being formed to interlock transversely to the plane of telescopic action, detents in the socket, locking means housed within the head having hook ends adapted to be engaged into said detents, and means for expanding and contracting said hook ends, substantially as specified.

5. A lock attached to the ends of the sections of a telescope-valve consisting in a socket attached to the under section, a head attached to the top section, the said head and socket being formed to telescope in the plane of telescopic action of the sections, and to interlock transversely thereto, detents in said socket, spring-actuated devices housed within the head, the ends of which are adapted to be engaged into the said detents, a collar within said head embracing said spring-actuated devices having a knob projected through a slot formed in the end of said top section, whereby the said springs are contracted and released from or into locking position, substantially as specified.

6. A lock for a telescope-valve, consisting of a socket attached to the end of the under section upon the interior face, detents in said socket, a head attached to the interior face of the upper section adapted to telescope within said socket and interlocking therewith transversely to the plane of telescopic action, locking means within said head adapted to be engaged into said detents, and means for releasing the same, substantially as specified.

7. In a telescoping valve, housing-heads attached to the ends of the top telescoping section, diverging springs having hooked ends projected through orifices in the opposite sides of said heads, sockets attached to the ends of the bottom telescoping section having a series of detents on its opposite sides adapted to be engaged by said hooked ends, the said heads having inclined under faces adapted to automatically slide by the detents without engagement when the sections are pressed together, said heads and sockets being formed to telescope and interlock against lateral strain, and means for controlling the locking position of said hook ends, substantially as specified.

8. In a telescoping valve, housing-heads attached to the ends of the top telescoping section, diverging springs having their converging ends secured within said housing-heads, a collar in each head encompassing said springs, each collar having a knob projected through a slot in the end of the top section exteriorly exposed, the springs having hooked ends projected through orifices in opposite sides of said housing when the collar is moved in one direction, and compressed within the housing when the collar is moved in the opposite direction, receiving-sockets attached to the ends of the bottom telescoping section having detents in the opposite sides adapted to be engaged by the hook ends of the springs when protruded through said heads, the heads and sockets being formed to telescope and interlock against lateral strain, and the hook ends being formed to interlock with the detents automatically when the valve-sections are closed apart, substantially as specified.

9. In a lock for a telescope-valve, a head inwardly projected from the end of the upper section, a locking member housed therein, the corresponding end of the under section being dovetailed in the plane of telescopic action, a socket inwardly projected from the edge of said dovetail and provided with detents to receive the locking member of the head, the said head and socket being formed to interlock transversely to the plane of telescopic action, substantially as specified.

10. A lock for a telescope-valve consisting of a head attached to the end of one section, the end of the opposing section being dovetailed, a socket projected from the edge of said dovetail in the direction of projection of the head, said head being formed to telescope and to interlock in said socket and dovetail, and means for locking said head and socket together, substantially as specified.

11. A head and socket attached to the corresponding faces of the ends of a telescope-valve, and extended therefrom in the same direction, said head and socket being formed to telescope and to interlock laterally, and means adapted to interlock said head and socket at any point in the plane of telescopic action, substantially as specified.

701,441. ENVELOP AND STAMP MOUNTING. CLARENCE H. WILLIAMS, Mayville, Ky. Filed Jan. 24, 1902. Serial No. 91,108. (No model.)

Claim.—1. An envelop and stamp mounter comprising a water-reservoir, a water-absorbent medium associated therewith, and a plunger provided near its extremities with parts, one of which is normally disposed without the reservoir, and the other normally disposed within the same, the first-named part, when the plunger is depressed, serving to supply air to the reservoir, and the second-named part to supply water to the said medium.

2. In an envelop and stamp mounter, the combination with a water-reservoir, of a nipple associated therewith and containing an absorbent material projecting at one end beyond the nipple, and a plunger provided with parts for supplying air to the reservoir and water to the nipple.

3. In an envelop and stamp mounter, the combination with a reservoir, of a nipple associated therewith and containing an absorbent material projecting at one end beyond the nipple, an open-work screen against which the said material bears, and a plunger provided with means for supplying air to the reservoir and water to the said material.

4. In an envelop and stamp mounter, the combination of a cylinder provided with a normally sealed water-filling inlet, a cap connected with one end of the cylinder and provided with a stuffing-box, a bottom secured within the opposite end and provided with a centrally-disposed orifice, a spring-actuated plunger working in the stuffing-box and in the orifice, and provided near its terminals with parts, one of which is normally in communication with the air and the other with the cylinder, a packing carried by the plunger and bearing against the under side of the bottom, a nipple associated with the cylinder and having its lower end constricted, an open-work disk screen carried by the nipple, and a sponge housed within the nipple and bearing against the under side of the screen and projecting beyond the constricted end of the nipple.

701,442. RAIL BRACE AND SUPPORT. HARRISON F. WILSON, Alhambra, Pa. Filed Nov. 20, 1901. Serial No. 94,128. (No model.)

Claim.—1. A rail-brace comprising a plate adapted to bear against the side of a tie and having lateral legs to rest upon the upper surface of the tie and a brace to bear upon the rail, the upper edge of the plate between the brace and one of the legs forming a rest for the rail to prevent crushing or indentation of the tie under the pressure of the rail, substantially as described.

2. A rail-brace comprising a plate adapted to bear against the side of a tie and having lateral legs to rest upon the upper surface of the tie and a rail-brace adjacent to one of said legs, the said upper edge of the plate between said brace and the opposite end leg forming a bearing-surface adapted to extend flush with or slightly above the upper surface of the tie to assist in supporting the rail, substantially as specified.

3. A rail-brace comprising a plate adapted to be secured to the

side of a tie and having an upper seat or bearing-surface for the rail, legs extending laterally therefrom to bear upon the upper surface of the tie, a brace to bear upon one side of the rail, and an auxiliary brace adapted to be secured to the plate and to bear upon the opposite side of the rail, substantially as and for the purpose set forth.

4. A rail-brace comprising a plate adapted to be secured to the side of a tie and having an upper seat or bearing-surface for the rail, legs extending laterally therefrom to bear upon the upper surface of the tie, a brace to bear upon one side of the rail, and an auxiliary brace adapted to be secured to the plate and to bear upon the opposite side of the rail, said auxiliary brace having a leg to rest upon the upper surface of the tie to supplement the action of the plate-legs, substantially in the manner set forth.

5. The combination with a tie and rail, of fastening-pieces secured to opposite sides of the tie and having braces to bear upon the opposite sides of the rail, said braces having their upper edges forming external bearing-surfaces for the rail and provided with legs resting upon the upper surface of the tie, substantially as specified.

701,443. TRANSFER OR CARBON PAPER FOR TYPE-WRITING MACHINES. HOWARD A. WILSON, New York, N. Y., assignor to Wyckoff, Macmaster & Beaudet, Inc., N. Y., a Corporation of New York. Filed Mar. 11, 1903. Serial No. 93,657. (No specimen.)

Claim.—Transfer-paper for use in type-writer manifolding, having one side coated with resin-ink and the other side coated with copying-ink, substantially as set forth.

701,444. APPARATUS FOR DYING YARN. CARL WOLZ, Schweinfurt-on-the-Rhine, Germany. Filed July 13, 1901. Serial No. 93,812. (No model.)

Claim.—1. Apparatus for dyeing yarn in the cap, comprising a polygonal vat, a false bottom therein having apertured seats for the caps, an inlet-port at one end above the false bottom extending nearly across the vat, and an exhaust-port in the bottom thereof; in combination with a pipe connected with said exhaust-port and having an outlet-terminal of gradually-increasing width connected to the aforementioned inlet-port and a suction and forcing device interposed in said pipe, substantially as and for the purpose set forth.

2. Apparatus for dyeing yarn in the cap, comprising a polygonal vat, a false bottom therein having apertured seats for the caps, an inlet-port of uniform vertical cross-sectional area at one end above the false bottom extending nearly across the vat, and an exhaust-port in the bottom thereof; in combination with a pipe connected with said exhaust-port and having an outlet-terminal of gradually-increasing width and of substantially the same vertical cross-sectional area as and connected to the aforementioned inlet-port, and a suction and forcing device interposed in said pipe, substantially as and for the purpose set forth.

701,445. SHEAVE-PROTECTOR. HARRY E. WOOD, Worcester, Mass. Filed Dec. 7, 1900. Serial No. 739,095. (No model.)

Claim.—A sheave-protector, comprising a blank curved throughout its length in the arc of a circle and provided at one end with elongated slots and at the other with elongated slots adapted to enter the grooves of the sheave and which they are turned to prevent their escape therefrom, the blank and slots arranged to diverge from a center coincident or approximately coincident with the center from which the arc of the blank is struck.

701,445.

701,446. CUTTING-CHOPPER. LEWIS W. WOOD, Worcester, Mass. Filed Dec. 26, 1901. Serial No. 97,739. (No model.)

Claim.—In a cotton-chopper, the combination with the main frame the forward end of which is provided with a chisel and an auxiliary attending device having one end attached to the chisel and the other end to the side of the main frame, of an axle journaled in the main frame and provided with a gear-wheel, a crank-shaft journaled in bearings in the main frame at points at the rear of the axle and provided with a gear-pinion meshing with said gear-wheel, a chopper-blade provided with a shank which is journaled upon said axle, and a guide-bracket fixed to the frame of the machine above the crank-shaft and provided with a hole through which the shank of the chopper-blade projects, cam-pieces 16 secured to the forward end of the machine and cam-pieces 17 secured to the rear end of the machine, substantially as set forth.

701,447. ROLLER-CUTTING-PRISM. FRED E. YAVNER, Rochester, N. Y., assignor to the Yavner & Sons Manufacturing Company, Rochester, N. Y., a Corporation of New York. Filed Jan. 14, 1903. Serial No. 94,164. (No model.)

Claim.—1. The combination with the side frame having the recesses and the ways at the sides thereof extending at an angle relatively

of the removable filling-pieces secured in the recesses and having corresponding ways therein, the journal blocks or beams operating in the ways and the cooperating rollers arranged in the frame.

2. The combination with the side frame having the recesses and the ways at the sides thereof extending at an angle relatively, of the removable filling-pieces secured in the recesses and having corresponding ways therein, the stationary bearing-blocks held between the frame and filling-pieces, the roller in said blocks and the movable bearing-blocks arranged between the filling-pieces and frame adjustable toward and from the roller, and rollers journaled in said last-mentioned bearing-blocks and co-operating with the first-mentioned roller.

3. The combination with the side frame having the recesses and the ways at the sides thereof extending at an angle relatively, of the filling pieces or blocks located in the recesses having the ways opposing them on the frame, a pressing-roller arranged near the intersection of the ways on the frame, bearing-blocks adjustable on both of the ways on the frame toward and from the first-mentioned roller, and rollers journaled in said bearing-blocks co-operating with said roller.

4. The combination with the side frame having the recesses provided with the vertically-extending ways, of the removable filling-pieces arranged in the recesses and having the corresponding ways or surfaces, a pressing-roller arranged at the lower portion of the ways, the vertically-movable journal-beams in the ways, the roller carried thereby co-operating with the first-mentioned roller, and means for adjusting the said blocks vertically.

5. The combination with the frame having the ways therein, the stationary removable bearing-blocks 35 at the ends of the ways, the roller journaled therein, the bearing-blocks 37 movable on the ways and the roller journaled therein and co-operating with the first-mentioned roller, of the bearing-blocks 36 and means for adjusting them on the ways, and an arbor journaled in the blocks 36 having means thereon for adjusting the blocks 37 in the ways.

6. The combination with the recessed side frame having the ways at one side of each of the recesses, and the arms extending over the ways, of the roller arranged at the lower end of the ways, the removable filling-pieces in the recesses, two sets of bearing-blocks arranged between the filling-pieces and the ways, a roller carried in the lower set of bearing-blocks, springs for raising them, and a rotary cam-shaft journaled in the upper blocks and operating upon the blocks of the roller.

7. The combination with the recessed side frame having the ways at one side of each of the recesses, the arms extending over the ways and the adjusting-curved, of the lower pressing-roller, the removable filling-pieces in the recesses, the two sets of bearing-blocks arranged between the filling-pieces and the ways, the upper pressing-roller carried in the lower blocks, springs for raising it and a rotary cam-shaft journaled in the upper blocks and operating upon the blocks of the roller.

8. The combination with the frame and ways therein, the stationary pressing-roller, the movable roller, the bearings therefor and the springs for separating the rollers, of the adjustable bearings in the ways, the pins operating on the bearings of the movable roller and guided in the last-mentioned bearings, the shaft journaled in said bearings having the cam-grooves in which the pins operate.

9. The combination with the frame and ways therein, the stationary pressing-roller, the movable roller, the bearings therefor and the springs for separating the rollers, of the adjustable bearings in the ways, the pins operating on the bearings of the movable roller and guided in the last-mentioned bearings, the shaft journaled in said bearings having the cam-grooves in which the pins operate.

10. The combination with the frame and ways therein, the stationary pressing-roller, the movable roller, the bearings therefor and the springs for separating the rollers, of the rotary shaft journaled in bearings and having the cam-grooves therein, the pins entering the cam-grooves and operating upon the bearings of the movable roller.

11. The combination with the frame and ways therein, the stationary roller, the adjustable roller, the bearings for the latter and springs for separating the rollers, of bearings above the movable roller, the shaft operating therein having the cam-grooves, and the pins guided in the bearings for the shaft, entering the cam-grooves and operating upon the bearings of the movable roller.

12. The combination with the frame and ways therein, the stationary roller, the adjustable roller, the bearings for the latter and springs for separating the rollers, of the bearings above the former bearings, means for adjusting and raising them, the rotary shaft journaled in said bearings having the cam-grooves, the pins guided in the bearings, projecting into the cam-grooves and operating upon the bearings of the movable roller.

13. In a roller cutting-prism, the combination with the frame, the stationary pressing-roller, the movable pressing-roller co-operating therewith and web-dampering device, of the internal toothed gear mounted on the end of the stationary roller, the bracket in the frame extending

beyond the gear, the crank-shaft journaled in the outer end of the bracket beyond the gear, having the pinion on its end engaging the internal gear, and pawl-and-rotchet mechanism for preventing the backward rotation of the roller.

14. The combination with the frame, the stationary pressing-roller, the movable pressing-roller cooperating therewith, web-dampening device, a web-take-up reel, and a ribbed roller arranged between the pressing-rollers and the reel, of the pulley on one end of the stationary roller, the belt connecting it with the reel, the internal gear and the pulley on said roller, the belt connecting the pulley with the ribbed roller, the bracket on the frame extending outwardly beyond the gear, the crank-shaft journaled in the bracket and the pinion on the end of the crank-shaft meshing with the gear.

15. The combination with the main frame having the ways, the roller therein, the bearing-blocks movable on the ways, the pressing-roller journaled therein cooperating with the first-mentioned roller, and springs for raising said blocks, of the bearing-blocks guided on the ways on the frame arranged above the last-mentioned ones, means for positively adjusting them toward the roller, and a straight bar journaled near its ends in said blocks and extending over the roller and provided with cones operating upon the bearings of the pressing-roller, and an operating-handle.

701,448. HILL-FILE. PHILIP H. YAWMAN, Rochester, N. Y., assignor to Yawman & Burt Manufacturing Company, Rochester, N. Y., a Corporation of New York. Filed June 3, 1901. Serial No. 68,868. (No model.)

Claim.—1. In a bill file or holder, the combination with a base-board or support, the slides thereon and a plate secured to the upper portion of one side, of a follower pivoted in the plate and having a cam-arm on the inner side of the latter, of the spring arranged exterior of the plate and extending through it and secured thereby and having the arm with which the cam-arm on the follower engages.

2. In a bill file or holder, the combination with the base-board or support, and plates at the sides thereof having two apertures, of the follower having the arms journaled in the plates and the crank at the end of one of them, and a spring-arm passing through one of the plate-apertures and having the extension parallel with the plate with which the crank-arm engages.

3. In a bill file, the combination with the base-board or support, and plates at the sides thereof having two apertures, of the follower having the arms journaled in the plates and having the extensions parallel with the plates and on the rear side thereof with which the cranks engage to hold the follower in two positions of adjustment.

4. In a bill file, the combination with the base-board or support, the slides and back board, and the plates at the upper portions of the side boards having apertures therein, of the follower having the arms journaled in the apertures in the plates, one of them being provided with a crank, and a spring-arm extending parallel with the plate to engage the crank-arm.

5. In a bill file, the combination with the base-board, the slides and back board, and the plates at the upper portions of the side boards having two apertures therein, of the follower having the arms extending through the apertures in the plates, and the crank thereon, the spring secured to the back board extending through the aperture in the plate and having the extension operating upon the crank on the follower-arm.

701,449. FILING-CAMMER. PHILIP H. YAWMAN, Rochester, N. Y., assignor to Yawman & Burt Manufacturing Company, Rochester, N. Y., a Corporation of New York. Filed Jan. 9, 1902. Serial No. 58,867. (No model.)

Claim.—1. The combination with a casing, of a slide or drawer ap-

erating therein having the base and provided with the front hinged thereon, a guide on one of the parts, an arm attached to the other part having the end lying beneath the guide, and a stop engaging the arm between its ends to limit the relative opening movement of the front.

2. The combination with a casing, of a base among therein having a front hinged thereon, a guide on one of the parts, and an arm attached to the other engaging the guide, a stop on the guide cooperating with the arm to limit the relative closing movement of the parts, and a stop on one of the parts engaging the arm between its ends to limit the opening movement of the parts.

3. The combination with a casing, of a slide or drawer mounted therein having the base, and a front pivoted thereon, a guide mounted on one of the said parts, and an arm pivoted to the other part having the end lying beneath the guide and adapted to engage one end thereof to limit the closing movement of the front and base, and a stop engaging the arm between its points of attachment to said parts to limit their opening movement.

4. The combination with a casing, of a slide or drawer movable therein having the base, and a front pivoted thereon, a guide mounted on one of the parts of the drawer having a notch therein, an arm attached to the other part having the end movable longitudinally on the guide and secured thereby and a shoulder on the arm adapted to engage the notch to prevent the movement of the arm on the guide.

5. In a slide or drawer for filing-cases, the combination with a base, and a front pivoted thereon, of a guide arranged upon one of the parts having a notch, an arm attached to the other part having the end movable laterally of the guide and provided with a shoulder adapted to engage the notch, and a stop on the arm adapted to engage the guide for limiting its lateral movement relative thereto.

6. In a slide or drawer for filing-cases, the combination with a base, and a normally vertically extending portion pivoted thereto at one end, of a guide mounted on one of the parts having a notch, an arm attached to the other part having the end lying beneath the guide and movable laterally thereof, a shoulder on said arm adapted to engage the notch, and a stop adapted to engage the guide for limiting the lateral movement of the arm thereon.

7. In a slide or drawer for filing-cases, the combination with a base, and a normally vertically extending and pivoted thereon, of a plate mounted on one of the parts having a slot, an arm pivotedly attached to the other part having the end opening in said slot and engaging the end thereof to limit the relative movement of the parts in one direction, and a stop on the plate engaging the arm between its ends to limit their movement in the opposite direction.

8. In a slide or drawer for filing-cases, the combination with the base, and an end portion pivoted thereto normally extending vertically therefrom, of a plate mounted on one of the parts of the drawer having a slot

and provided with a notch, a spring-arm having a shoulder and pivoted to the other member and movable laterally of the plate to cause the shoulder to engage the notch, and a projection on the arm operating in the slot.

9. In a slide or drawer for filing-cases, the combination with a base, and a portion forming a wall pivoted at the edge thereof, of a plate on one of the parts having the slot and provided with a notch, an arm pivoted to the other part having the end operating in the slot, and a shoulder on the arm, means normally moving the arm toward one side of the plate to engage the shoulder with the notch, and a stop on the arm adapted to engage the opposite side of the plate to limit its lateral movement when the shoulder is disengaged from the notch.

10. In a slide or drawer for filing-cases, the combination with a bottom portion, and a wall pivoted at the end thereof, a base-plate secured to one of said parts of the drawer having a flange provided with the slot, a brace-arm pivoted at one end to the other part of the drawer having its opposite extremity projecting laterally through the slot and adapted to engage the inner end of the slot to limit the relative closing movement of the front and base, and a stop at the outer end of the base-plate engaging the arm between its ends to limit their relative movement in the opposite direction.

11. The combination with a casing having a drawer-aperture, a slide movable therein, and a wall adapted to normally close the aperture, of pivotal connections between the slide and wall, and adjustable devices between the slide and front whereby the latter may be moved at an angle to the former above the plane of the slide or substantially in line therewith.

12. The combination with a casing having an aperture, a slide movable therein, and a wall normally closing the aperture and extending over the end of the slide, of hinge connections between the slide and wall, a guide on one of the parts of the drawer, a brace-arm having the end engaging the guide and attached to the other part, and a stop engaging the arm and arranged out of line with the pivotal center of the hinge connections to limit the relative opening movement of the front on the base.

13. In a slide or drawer for filing-cases, the combination with a base, of a wall therefor forming the front of the drawer thicker than the base, and provided with a recess and having the tongue at its lower edge extending over the end of the base, a hinge having one member attached to the base and the other cut into the recess in the front wall whereby when the parts of the drawer are opened the outer surfaces of the base and front will be in substantial alignment, and adjustable devices between the parts for limiting their opening and closing movement.

14. The combination with a cabinet or casing having an opening therein, of a removable slide arranged in said opening embodying a base, a front hinged at its lower edge to said base and adapted to form a closure for the casing and to be moved into substantial alignment with the base, a brace-arm pivotally connected with one of said parts and sliding upon the other, and stops for limiting the movements of said parts on the hinge.

701,450. ARTIFICIAL LIMB. HENRY YEARMAN, North Manchester, England. Filed Oct. 14, 1900. Serial No. 22,193. (No model.)

Claim.—1. In combination, an artificial limb having cavities within it, a bent lever within the knee-cavity and with one end mounted on the pin which joins the upper and fore legs and the other end connected to a pin within the upper leg, a curved link connected at one end to the said lever at its bend and at the other to an artificial tendon made of catgut, a tension device within a cavity in the fore-leg consisting of two stationary and one moving plate and two rods, also a rubber washer between two of the plates and to one of which plates the said tendon is attached, a further artificial tendon secured to one of the fixed plates of the tension device and to the two part of the limb, substantially as and for the purposes set forth.

2. In combination, an artificial limb with cavity, a tension device within the cavity consisting of two plates and rubber washers between them, an artificial tendon secured to one plate and passing through the other plate at one end and at the other end attached to the two-piece of the limb, as and for the purposes set forth.

701,451. WHEELER. LEVI D. YOUNG, DALLAS, TX. Filed Oct. 13, 1901. Serial No. 72,822. (No model.)

Claim.—A implement of the character described formed of a series of wires doubled upon themselves and twisted together for a short distance

from the fold and having the end portions spread and bent to form teeth and having an eye at the fold and another in the length of the stem formed by opening adjacent twists, a handle receiving the stem of the tool, and fastenings connecting the handle and stem by passing through the eyes of the latter and openings in the handle, substantially as specified.

701,452. DRAWING-OFF TAP FOR AERATED LIQUIDS. BENJAMIN YOUNG, Glasgow, Scotland. Filed Jan. 22, 1902. Serial No. 60,776. (No model.)

Claim.—1. A drawing-off tap for aerated liquids, comprising a measuring vessel, a vertical plug-cock fitted in the vessel with its narrow end upward, a barrel for the cock, packing and a screwed nut to hold the cock to its seat in the barrel, in combination with an air-passage, inlet and discharge passages in the barrel of the plug-cock, a main passage in the plug-cock to connect the measuring vessel with either a reservoir or a discharge-opening, and a second passage in the plug to connect the measuring vessel with the atmosphere, substantially as described.

2. In drawing-off taps for aerated liquids, in combination a measuring vessel, a vertical plug-cock fitted thereto with its narrow end upward and held to its seat by packing and a screwed nut, inlet and discharge passages in the barrel of plug-cock, a main passage extending through the plug from the level of the inlet and discharge to the interior of the measuring vessel; and a second passage in the plug connected at its upper end with a pipe extending up within the measuring vessel and having its lower end at the level of a passage through the barrel open to the atmosphere, substantially as and for the purposes herein set forth.

3. A tap and measuring vessel for drawing off aerated liquids, comprising a barrel, a measuring vessel above said barrel, a cylindrical vertical central opening in the barrel, ports opening from the barrel outward, one to the reservoir, one to the atmosphere and one forming a discharge, a vertical plug in the cylindrical opening, a part therein adapted to be connected with the reservoir or the discharge, a groove adapted to be connected with the atmosphere-opening in the barrel and a tube carried by said plug extending into the measuring vessel and connecting with said groove, substantially as described.

4. A tap and measuring vessel for drawing off aerated liquids, comprising a barrel, a measuring vessel above it, a cylindrical tapered vertical plug within the barrel, said plug having its end of lesser area upward, a spindle at its other end and a nut to hold it in place, the plug having an opening I and a groove P and carrying an upwardly-extending tube, the barrel having an opening to the atmosphere, an opening to the container and a discharge-opening, as and for the purposes set forth.

701,453. CARBON-SORTING MACHINE. MARION M. ZELLMER, Cleveland, Ohio, assignor to National Carbon Company, Cleveland, Ohio, a Corporation of New Jersey. Filed Feb. 15, 1902. Serial No. 64,172. (No model.)

Claim.—1. In combination, an electric circuit, means for inserting carbon rods therein, means for determining the resistance thereof, and automatic means for guiding said rods to different receivers, substantially as described.

2. In combination, an electric circuit, means for inserting carbon rods in said circuit, automatic means for guiding said rods therefrom, said last means being controlled by the electrical resistance of said rods, substantially as described.

3. In combination, an electric circuit, means for inserting carbon rods in said circuit, receivers, means for guiding said carbon rods, said last means being controlled by the resistance of said carbon rods, substantially as described.

4. In combination, an electric circuit, means for inserting carbon rods in said circuit, means for comparing their resistance with a standard resistance, receivers, means for guiding said carbon rods, means for controlling said last means by the electrical resistance of said carbon rods, substantially as described.

5. In combination, an electric circuit including two branches, one of said branches containing a known resistance, means for inserting carbon rods in the other of said branches, a bridge-circuit connecting points of said branches and means controlled by the current flowing in said bridge-circuit for guiding said rods to receivers, substantially as described.

6. In combination, an electric circuit, means for inserting carbon rods in said circuit, means for comparing their resistance with a standard resistance, receivers, means for guiding said carbon rods, means for controlling said last means by the resistance of said carbon rods, substantially as described.

7. In combination, an electric circuit including two branches, a bridge connecting points of said branches, an electrically-controlled apparatus located in said bridge, a second circuit controlled by said apparatus, means for inserting carbon rods in one of said branches, means for guiding said rods in passing out of said circuit, said last means being controlled by said second circuit, substantially as described.

8. In combination, an electric circuit including two branches, one of said branches containing a known resistance, means for inserting carbon rods in the other of said branches, a bridge-circuit connecting points of said branches, means for guiding said carbon rods to different receivers, galvanometer located in said bridge-circuit, means whereby said galvanometer may close a second electric circuit, and means whereby the closing of said second circuit may guide said carbon rods to different receptacles, substantially as described.

9. In combination, an electric circuit including two branches, one of said branches containing a known resistance, means for inserting carbon rods in the other of said branches, a bridge-circuit connecting points of said two branches, a second electric circuit, means whereby a current flowing in said bridge-circuit may close said second circuit, means for guiding said carbon rods in different receptacles, said means being controlled by said second circuit, substantially as described.

10. In combination, an electric circuit including two branches, one

of said branches including a known resistance, means for inserting carbon rods into the other of said branches, a bridge conductor connecting points of said branches, a galvanometer therein, a second circuit, means whereby said second circuit may be closed by a movement of the needle of said galvanometer, means for guiding said carbon rods to different receptacles, said means being controlled by said second circuit, substantially as described.

11. In combination, an electric circuit including two branches, one of said branches having a known resistance, means for inserting carbon rods in the other of said branches, a bridge conductor connecting points of said two branches, said bridge conductor including a galvanometer, a second electric circuit including the spindle of said galvanometer, a contact-arm carried by said spindle, whereby the needle of said galvanometer may close said second circuit through said arm, means for guiding said carbon rods to different receptacles, said means being controlled by said second circuit, substantially as described.

12. In combination, an electric circuit, members forming terminals thereof and adapted to receive carbon, means for feeding electric-light carbon rods to said members, means for withdrawing said carbon rods from said members, receivers therefor, means for advancing said carbon rods to said receivers, and means for guiding said carbon rods to said receivers, said last means being controlled by the resistance of said carbon rods, substantially as described.

13. In combination, an electric circuit, jaws forming terminals thereof and adapted to grasp a carbon, means for feeding carbon between said jaws, means for closing said jaws, means for releasing said jaws, means for guiding said carbon, and means whereby said last means is controlled by the resistance of said electric-light carbon rods, substantially as described.

14. In combination, an electric circuit, means for inserting carbon between the terminals thereof, a second electric circuit, means whereby the resistance of said carbon controls the condition of said second circuit, means for guiding said carbon when advanced from said terminals, said guiding means being controlled by said second circuit, substantially as described.

15. In combination, an electric circuit including two branches one of said branches including a known resistance, means for advancing carbon into a position between terminals in the other of said branches, a bridge conductor connecting points of said branches, receivers, means for advancing said carbon toward the same, means for guiding said carbon to said receivers, said last means being controlled by the flow of current in said bridge conductor, substantially as described.

16. In combination, an electric circuit, means for feeding carbon between terminals thereof, means for advancing said carbon therefrom, receivers, a guide-plate, means whereby said guide-plate determines the direction of said carbon with respect to said receivers, and means whereby the resistance of said carbon determines the position of said guide-plate, substantially as described.

17. In combination, an electric circuit, means for feeding carbon one by one between terminals of said circuit, automatic means for advancing said carbon, receivers, means for guiding said carbon with respect to said receivers, said last means being controlled by the resistance of said carbon, substantially as described.

18. In combination, an electric circuit, means for feeding carbon between terminals thereof, means for comparing the resistance of said carbon with a standard resistance, receivers, means for advancing said carbon, means for guiding said carbon into said receivers, and means whereby said last means is controlled by the resistance of said carbon, substantially as described.

19. In combination, a support adapted to receive a plurality of carbon, feeders, means whereby said feeders may advance said carbon from said support, members adapted to contact said carbon, an electric circuit, said members constituting terminals for the same, receivers, means for guiding said carbon to the same, said last means being controlled by the resistance of said carbon, substantially as described.

20. In combination, feeders adapted to support carbon, retaining-fingers for said carbon, means for moving said feeders so that they may engage one of said carbon, members adapted to grasp said carbon, said members constituting terminals for an electric circuit, and automatic means for withdrawing said carbon from said members, substantially as described.

21. In combination, feeders adapted to support carbon, retaining-fingers therefor, means for moving said feeders so that the supporting-fingers thereof pass from beneath the extremities of said carbon, whereby said feeders may remove said extremities of carbon, members adapted to grasp said carbon, said members constituting terminals for an electric circuit, and means for withdrawing said carbon from said members, substantially as described.

22. In combination, feeders adapted to support carbon, retaining-fingers therefor, means for moving said feeders so as to segregate one of said carbon, arms constrained against said segregated carbon, where it is retained by said feeders, members adapted to grasp said carbon, said

members constituting terminals for an electric circuit, means for withdrawing said carbon from said members, and means for advancing the same, substantially as described.

23. In combination, feeders having supporting-fingers, retaining-fingers therefor, whereby carbon rods may rest thereon, means for moving said feeders so that said supporting-fingers pass from beneath one of said rods, whereby it may be segregated from the rest, said feeders having an edge substantially perpendicular to their supporting-fingers, spring-constrained arms adapted to press the segregated rod against said edges, means for moving said feeders to bring said rod adjacent to the terminals of an electric circuit, means whereby said terminals may grasp said rod, means for withdrawing said rod from said terminals, and means for advancing the same, substantially as described.

24. In combination, feeders, means for supplying carbon thereto, one by one, means whereby said feeders may advance said carbon to a point adjacent to the terminals of an electric circuit, means whereby said terminals may grasp said carbon, means for releasing the same therefrom, automatic means for advancing said carbon, receivers, means for guiding said carbon thereto, said means being controlled by the resistance of said carbon.

25. In combination, pivoted feeders having circumferential supporting-fingers upon which carbon may rest, means for rocking said feeders so that said supporting-fingers pass from beneath one of said carbon, whereby a carbon may be segregated, said feeders having a substantially radial edge, spring-constrained arms adapted to press a segregated carbon against said edge, means for rocking said feeders so that said segregated carbon is advanced, an electric circuit, the terminals whereof may grasp said carbon, means for releasing the same therefrom, means for advancing said carbon, means for guiding them, receivers into which said carbon may pass, said guiding means being controlled by the resistance of said carbon, substantially as described.

26. In combination, pivoted feeders having circumferential supporting-fingers adapted to support a plurality of carbon, retaining-fingers therefor, means for rocking said feeders so that said supporting-fingers may pass from beneath one of said carbon, whereby one of said carbon may engage said feeders, means for rocking said feeders so as to advance said carbon, jaws adapted to grasp the ends thereof, said jaws constituting terminals of an electric circuit, means for advancing said carbon therefrom, means for guiding said carbon, receivers into which said carbon may pass, said guiding means being controlled by the resistance of said carbon, substantially as described.

27. In combination, an inclined support adapted to receive a plurality of carbon, retaining-fingers, feeders adapted to support some of said carbon, means for moving said feeders so that one of said carbon may be engaged thereby, an electric circuit, means whereby said carbon may advance said carbon to a point adjacent to the terminals of said circuit, means whereby said terminals may grasp said carbon, means for withdrawing said carbon therefrom, receivers therefor, means for guiding said carbon thereto, said last means being controlled by the resistance of said carbon, substantially as described.

28. In combination, pivoted feeders having circumferential upper faces adapted to support carbon, said feeders having shoulders adapted to engage and segregate one of said carbon, pivoted arms constituting said segregated carbon against said shoulders, terminals of an electric circuit between which said segregated carbon is deposited, said feeders having curved faces adjacent to said shoulders, and said arms having curved faces adapted to cooperate therewith, whereby said carbon may be raised and advanced from said terminals, substantially as described.

29. In combination, an inclined board, retaining-fingers adapted to maintain a plurality of carbon thereupon, pivoted feeders having circumferential faces adapted to support the lowermost of said carbon, said circumferential faces having recesses, means for rocking said feeders so that the extremities of said carbon may pass into said recesses, arms adapted to be constrained so as to maintain a carbon within said recesses, jaws adapted to receive said carbon, an electric circuit including said jaws as terminals, said feeders having curved faces adjacent to said recesses, and said arms having curved faces adapted to form guides for said carbon, said feeders and arms cooperating, whereby said carbon may be raised from said jaws and advanced, substantially as described.

30. In combination, a support adapted to receive carbon, feeders adapted to advance said carbon one by one from said support, an electric circuit, jaws forming terminals thereof and adapted to receive said carbon, mechanism adapted to close said jaws, said mechanism including a spring through which the operating force is applied, substantially as described.

31. In combination, a support adapted to receive a plurality of carbon, feeders adapted to advance said carbon from said support, jaws adapted to receive said carbon when so advanced, said jaws constituting terminals for an electric circuit, mechanism for opening and closing said jaws, said mechanism including a link and a spring carried by said

link, through which the operating force for said jaws is transmitted, substantially as described.

32. In combination, a hopper adapted to receive carbon, a cylinder having grooves which may receive said carbon, means for rotating said cylinder so as to feed said carbon one by one from said hopper, an inclined table upon which said carbon are delivered, retaining-fingers against which said carbon may rest, feeders adapted to advance said carbon one by one from said table, an electric circuit having terminals adapted to receive the ends of said carbon, means for withdrawing said carbon from said terminals and advancing the same, receivers, means for guiding said carbon thereto, said guiding means being controlled by the resistance of said carbon, substantially as described.

33. In combination, a hopper adapted to receive carbon, means for feeding said carbon one by one from said hopper, an inclined table upon which said carbon are delivered, retaining-fingers upon said table, pivoted feeders adapted to form supports for the extremities of said carbon, means for rocking said feeders so that they may engage the extremities of said carbon, terminals adapted to receive the extremities of said carbon, said feeders having curved faces, guides adapted to cooperate therewith so that said carbon may be raised and advanced from said terminals, receivers, means for guiding said carbon thereto, said guiding means being controlled by the resistance of said carbon, substantially as described.

701,454. FOUR-WHEEL EQUALIZER. EDWARD SCHLAEGER and FREDERICK SCHLAEGER, Oakland, Iowa. Filed Apr. 2, 1902. Serial No. 100,100. (No model.)

Claim.—The combination with a pivot-beam provided with a suitable clevis, of a bolt passing through said clevis, a draft-bar extending rearward and downward from said clevis-bolt, a loop positioned upon one side of said clevis, two depending yoke members adjustably clamped to said pivot-beam, a forward draft-bar being secured to said yoke members, a connecting-link secured to the lower end of said draft-bar, a swivelled car supported by said yoke members, a main rod secured to said swivelled car and extending through a forward loop, a main tree pivotally secured to the forward end of said main rod, a loop extending from a rearward main tree at one end, a curved lever passing through said last-mentioned loop and extending approximately parallel with a forward main tree, a connecting-bar pivotally secured approximately centrally to said curved lever, a toggle-bar pivotally secured to said last-mentioned connecting-bar, a centrally-pivoted connecting-bar extending from one end of said curved lever and being centrally pivoted to said toggle-bar and secured at the remaining end to a rearward connecting-link, a second connecting-bar extending forward from a rearward centrally-pivoted toggle-bar, a curved bar pivotally secured near one end to said last-mentioned connecting-bar, two connecting-rods extending from the ends of said curved bar and coupling one another and being pivotally secured to a rearward main tree, a double-bar pivotally secured to a rearward main tree near one end, two bolts secured to said main tree near the remaining end of said main tree, a chain passing over said bolts and provided at each end with a shackle, all arranged substantially as and for the purpose set forth.

701,455. CONTROLLER. THOMAS VAN SWINSEN, Preston, England. Filed Jan. 22, 1902. Serial No. 90,992. (No model.)

Claim.—1. In a controller, in combination, a shaft, a collar tightly surrounding the shaft and having an annular groove in its upper surface, with an outlet through the peripheral wall of the groove, and a trough or discharge-plate directly beneath said outlet when the shaft is at the off position, substantially as described.

2. In a controller, in combination, a frame, a cover therefor, a vertical shaft within the frame and extending through the cover, a substantially horizontal plate carried by the frame beneath the cover, a bearing carried at the front edge of said plate in which said shaft is journaled, there being a flange along the front edge of said plate, and a collar rigid on the shaft having in its upper surface an annular groove or recess discharging when the shaft is in the off position to the rear above said plate, substantially as described.

3. In a controller, the combination of a shaft, a metal tube carried by the shaft and surrounding the same and insulated from it, and metal segments having hubs snugly embracing said tube and electrically connected thereby, substantially as described.

4. In a controller, the combination of a shaft, metal tubes carried by the shaft and surrounding the same and insulated from the shaft and from each other, and metallic segments having hubs snugly embracing said tubes, substantially as described.

5. In a controller, the combination of a metal shaft, insulating-films surrounding the same, metal tubes surrounding the films, insulating-washers between the tubes, and metal segments having hubs snugly embracing the metal tubes, substantially as described.

6. In a controller, in combination, a shaft, wooden sectional sleeves collectively surrounding the same, metal tubes surrounding the wooden sleeves, and segments carried by the tubes, substantially as described.

7. In a controller, in combination, a flattened shaft, wooden sectional sleeves collectively surrounding the same and presenting a cylindrical exterior, metal tubes snugly embracing such sectional sleeves, insulating-washers between the tubes, and segments having metal hubs snugly embracing said metal tubes, substantially as described.

8. A segment for a controller including a peripheral portion, a hub portion, and an arm connecting them, combined with a removable tip having a rubbing portion, an inwardly-extending leg, and a screw clamping said leg to said arm, substantially as described.

9. A segment for a controller comprising a hub portion, a rubbing portion and an arm connecting them, and a threaded bar carried by said arm, combined with a removable tip having a rubbing portion adapted to slide with the rubbing portion of the segment, and having an inwardly-extending leg, and a screw passing through said leg into said threaded bar, substantially as described.

10. In a controller, the combination with a segment-cylinder, of a stationary bracket, a contact-finger having a spring-shank carried thereby, a stop for limiting the outward movement of the finger, and a screw securing both said stop and finger in the bracket, substantially as described.

11. In a controller, in combination, a stationary bracket, a contact-finger having a spring-shank, a stop in the form of a bent plate, and a screw passing through both said stop and shank into the bracket, the free end of said bent plate standing a short distance behind said finger, substantially as described.

12. In a controller, in combination, a stationary bracket, a contact-finger having a spring-shank, a safety-stop bracket for limiting the outward movement of the contact-finger, a screw passing through said stop-bracket and said spring-shank into the stationary bracket for holding said finger to the stationary bracket, an inward stop-leg carried by the stationary bracket, and an adjusting-screw carried by the contact-finger and adapted to engage therewith, substantially as described.

13. In a controller, the combination with contact segments and fingers, of a hinged and reversible solenoid blow-out, substantially as described.

14. In a controller, the combination with contact segments and fingers, of a hinged blow-out, and means whereby the swinging of said blow-out on its hinge breaks the electrical connection thereto, substantially as described.

15. In a controller, the combination with contact segments and fingers, of a hinged and reversible solenoid blow-out comprising coils within separated insulating-bases and connected in series and terminals for the collective coils carried by the blow-out, and other terminals with which these automatically disengage when the blow-out is swung on its hinge, substantially as described.

16. In a controller, the combination of blow-out coils contained within insulated boxes, insulating spacing-blocks between the boxes, metallic rods passing through the boxes and spacing-blocks, hinges for supporting the whole construction, and a lock for holding it in place, substantially as described.

17. In a controller, the combination of blow-out coils contained within insulated boxes, insulating spacing-blocks between the boxes, metallic rods passing through the boxes and spacing-blocks, hinges for supporting the whole construction, and metal strips carried by the solenoid and forming the terminals of the coils thereof, and stationary members with which they are adapted to connect when the solenoid is in a closed position, substantially as described.

18. In a controller, the combination of a series of coils contained within insulating-bases, insulating distance-blocks between the boxes, rods passing through the boxes and blocks, a fiber plate above the top box, and a fiber plate below the bottom box, said rods passing through said plates and clamping the whole together, a pair of hinge members carried stationary with the controller-frame, said hinge members being pivotally connected to said fiber plates, terminals of the solenoid carried by said plates respectively, and cooperating terminals adapted to engage the same when the solenoid is in a closed position, substantially as described.

19. In a controller, a movable blow-out, combined with three terminals, and means whereby one terminal is connected with one end of the blow-out and the other two terminals are connected with the other end of the blow-out when the blow-out is in place, all of said terminals being automatically disconnected from each other and from the blow-out when the blow-out is removed, substantially as described.

20. A controller and its circuit presenting three terminals adjacent to a blow-out, combined with each blow-out which is a solenoid composed of a series of coils in a hinged structure and having two terminals in the form of metallic plates, one adapted to engage one of said circuit-terminals the other adapted to engage both of the remaining terminals mentioned in one position of the solenoid, said terminals being all disconnected in another position of the solenoid, substantially as described.

21. A series-parallel controller, including a pair of contact-fingers, one adapted to be in engagement at the final series position, and both in engagement at the final parallel position, conductors leading from said fingers to adjacent terminals, combined with a movable solenoid having its coils terminating in contact members, one of which is adapted to engage and bridge said two adjacent terminals, and the other of which is adapted to engage a terminal from the governing resistance, substantially as described.

22. A controller having contact segments and fingers, and circuits leading from the fingers, combined with a blow-out consisting of a series of coils contained in boxes adapted to project between the fingers, said boxes being rigidly held apart in a hinged structure, means for locking said hinged structure in position, a pair of contact-strips carried by said hinged structure to form terminals for the two ends of the series of coils, and contact members carried by the controller to form the terminals of some of its circuits and adapted to be engaged by said strips, whereby when the solenoid is swung on its hinge the electrical connection to each end thereof is broken, substantially as described.

23. In a solenoid blow-out, the combination of a coil of conductor, and sheet-metal plates of magnetic material on opposite sides of the conductor out of contact therewith, substantially as described.

24. In a solenoid blow-out a recessed insulating-box, a coil of metallic ribbon within said box, a pair of sheet-metal plates of magnetic material within said box on opposite sides of the coil, and parallel with the opposite sides of the boxes, said plates being insulated from the coil, substantially as described.

25. In a controller, the combination of a frame and a cover therefor, of a hook for locking the cover to the frame, which hook comprises a housing portion secured to the cover near the edge thereof, a hook pivoted thereto, and a spring carried by the housing and tending to force the hook into either of its extreme positions, substantially as described.

26. In a controller, the combination of a frame, a hinged sheet-metal cover therefor, a housing riveted to the cover near the free edge thereof, a hook pivoted in said housing and adapted to engage a lug on the rear side of the frame, said hook having a projecting toe, and a half-spring within the housing and secured to it and bearing against said toe, said toe being adapted to have either of two surfaces in contact with the spring according to the position of the hook whereby the hook is given a tendency to assume either of its extreme positions, substantially as described.

701,456. CONTROLLER. THOMAS VAN SWINSEN, Preston, England. Filed Jan. 22, 1902. Serial No. 90,993. (No model.)

Claim.—1. An electric switch having a movable insulating-body with a longitudinal recess in it, a pair of separated contact-plates secured to the outer surface of said body, a metallic bar rigidly connected to each of said plates on their inner sides and occupying such recess, and insulating material filling the outer portion of each recess, substantially as described.

2. In an electric switch, in combination, a cylindrical wooden body, a pair of parallel recesses on one side thereof, separated segments on that side of the body extending across both recesses, a pair of longitudinal bars joining alternate members of said segments on the inner sides thereof, one bar occupying one recess and one the other, substantially as described.

3. In an electric switch, in combination, a cylindrical wooden body, a pair of parallel recesses on one side thereof, separated curved plates on that side of the body extending across both recesses, screws passing through the plates into the body, a pair of longitudinal bars joining alternate members of said segments on the inner sides thereof, one bar occupying one recess and one the other, and insulating material filling the remainder of said recesses, substantially as described.

4. In an electric switch, the combination of a cylindrical wooden body having a pair of parallel longitudinal recesses on the same side thereof, four contact-segments extending acrosswise of said recesses, two wider seg-

ments on the opposite side of the body, screws passing through said segments into the body for holding the segments in place, and a pair of longitudinal bars connecting alternate members of said four segments, said bars being on the inner sides of the segments, and rigidly connected therewith and occupying said recesses, and insulating material filling the space in the recesses in front of said bars and behind those segments which the bars cross but do not engage, substantially as described.

5. The combination with a rotatable reversing-switch body, an automatic spring-actuated lock independent of the operating-lever of the switch, which lock is adapted to engage a shoulder movable with the body when it is turned to the emergency position and prevent its return therefrom until the lock is extraneously released, substantially as described.

6. The combination of a body adapted to be turned on its axis and carrying contact-segments, an abrupt shoulder on said body, a dog spring-pressed against a smooth surface adjacent to said shoulder and adapted to engage the shoulder when the switch-body is turned into the emergency position, and means for releasing said dog, substantially as described.

7. The combination of a switch having a body adapted to be turned and carrying contact-segments, a collar on said body having an abrupt shoulder, a dog normally engaging the periphery of said collar, a spring constraining said dog in said position, said dog being adapted to engage said abrupt shoulder when the switch comes to a certain position, and means independent of the operating-lever of the switch for releasing said dog, substantially as described.

8. The combination with a controller-frame and a movable switch-body carried thereby, of a housing carried by the frame, a dog pivoted in said housing, a push-button slidable through the frame and adapted to operate said dog in one direction, a spring tending to move the dog in the other direction, said dog cooperating with said movable switch-body to lock the same at a certain position thereof, substantially as described.

9. The combination of a controller-frame, a housing carried thereby, a dog pivoted to said housing, a spring within the housing bearing against one side of the dog, a push-button movable through the housing and bearing against the other side of the dog, a reversing-switch carried by the controller-frame, a smooth peripheral surface rigid with the movable member of said switch, which surface the nose of said dog normally engages, said surface having an abrupt termination providing a shoulder with which the dog may lock under the influence of said spring and from which it may be released by said push-button, substantially as described.

10. The combination with a motor, electric circuits and contact-fingers at which they terminate, of a reversing-switch body adapted to move with reference to said contact-fingers to reverse said motor, said body having three different positions, namely, an ahead position, a reverse position, and an emergency-brake position, said last position completing the circuits the same as to drive the motor in the reverse direction but connecting an additional circuit to close the motor on itself, substantially as described.

11. A reversing-switch, comprising a series of contact-fingers, and two series of contact-plates on a relatively movable body, one series being adapted to connect adjacent fingers and the other series alternate fingers, each of said series having an extra narrower plate connected with one of the other plates and adapted to engage a certain finger in one position but not all operative positions of the switch, the fingers cooperating with such narrower plates being connected with lines leading from one side of the motor, and the fingers cooperating with the plates with which such narrower plates are connected being connected to lines leading from the other side of the motor, whereby an emergency position is provided where the motor is closed on themselves, substantially as described.

12. The combination with a motor, electric circuits and contact-fingers at which they terminate, of a reversing-switch body adapted to move with reference to said contact-fingers to reverse said motor, said body having four different positions, namely, an ahead position, an off position, a reverse position, and an emergency-brake position, said last position completing the circuits the same as to drive the motor in the reverse direction but connecting an additional circuit to close the motor on itself, and an automatic lock coming into action at said fourth position and adapted to prevent the accidental movement of the reversing-switch body from such emergency-brake position, substantially as described.

13. A reversing-switch having four positions, namely, ahead, off, reverse, and emergency, and comprising two series of contact-fingers, and two series of contact-plates on a relatively movable body, one series of plates being adapted to connect adjacent contact-fingers and the other series alternate fingers, and each of said series of plates being adapted to engage either of said series of fingers, the other series of plates concurrently engaging the other series of fingers, said series of plates having extra members located intermediate of the lines of engagement of said plates at the ahead and reverse positions, and contact-fingers for said extra members, whereby said extra members are engaged by their contact-fingers in the emergency position but not in the other operative positions of the switch, substantially as described.

14. In a controller, a casing, a reversing-switch within the casing comprising contact-fingers and a relatively movable body, said body having four different positions, namely, ahead, off, reverse and emergency, combined with a lock within the controller-casing and carried one member by said movable body and the other by the controller-frame, and adapted to automatically lock said switch-body in the emergency position, and means extending through the casing for releasing said lock, substantially as described.

701,457. APPARATUS FOR OBTAINING ZINC OR OTHER VOLATILE METALS FROM ORES OR MATTER. JOHN ARMSTRONG, London, England. Filed Aug. 30, 1900. Serial No. 30,309. (No model.)

Claim.—1. In a furnace for reducing volatile metals, the combination of a central column for the charge of mixed ore and fuel, side columns for the fuel, a reduction-chamber below into which they all converge, a large number of tuyeres or blast-orifices around the reduction-chamber whereby the blast is broken into minute streams, and therefore quickly dissipated, a condensing device and exit-passages for the effluent gases direct to the condenser close adjoining, whereby the blast attacks evenly a layer of fuel below the part intermediate between the charge and the condenser, and raises the fuel above to a high heat and the effluent gases pass through this incandescent fuel above the hottest heating zone on their way to the condenser and the carbonic dioxide is changed to carbon monoxide before it is cooled.

2. In a furnace for smelting ores containing zinc, the combination of a reducing-chamber, means for feeding the charge thereto, a vessel containing a bath of zinc, means for keeping the zinc therein in a comparatively cool and liquid state and a passage for the vapors from the reduction-chamber through a still hotter part of the furnace into and below the surface of the liquid metal.

3. In a furnace for reducing ores containing zinc, the combination of a central column-chamber for the charge of mixed ore and carbon, side column-chambers for the fuel, a central reduction-chamber below into which all converge, numerous tuyeres on the sides of the reduction-chamber, a central dump below having a tapping device, an exit for the fumes through the fuel placed below the side column-chambers and a bath containing molten zinc into which the said exit dips, whereby the zinc-vapor is volatilized and condensed in the liquid zinc and the less volatile metals collect in the dump.

4. In a furnace for reducing ores containing zinc, and other metals, the combination of a central reducing-chamber, means for supplying fuel at the sides, means for supplying ore at the center, numerous tuyeres for supplying air through the fuel at the sides to the ore, means for drawing off and means for condensing the zinc-vapors, a dump below for the less easily volatilizable metals to collect in and means for introducing fumes a little above the fluid metal in the dump, but below the main portion of the zone of reduction.

5. The combination of a reducing-chamber, a vessel containing a bath of zinc, of means for heating the fuel between the reducing-chamber and said bath to a high degree, means for passing the zinc-vapors from the reducing-chamber through such highly-heated fuel to the bath of zinc, an exit below the surface of the fuel direct into said bath below the normal surface of the metal, and means for keeping the bath of metal at a temperature a few degrees above its fusing-point.

6. In a furnace for smelting zinc ores, the combination of the chambers *a* & *b* for the purposes described, the water-jackets *c* surrounding the space below said chambers giving a converging direction to the three columns *e* & *f*, the tuyeres *g* passing through the water-jackets and formed of a vast number of small tubes, and the dump *h* at the lowest point for the purposes described.

701,458. PROCESS OF OBTAINING ZINC OR OTHER VOLATILE METALS FROM ORES OR MATTER. JOHN ARMSTRONG, London, England. Filed Aug. 30, 1900. Serial No. 30,370. (No specimens.)

Claim.—1. The process of smelting compounds of volatile metals such as described, which consists in heating them with carbon out of contact of air, reducing and vaporizing them in a reducing atmosphere, consisting largely of carbon monoxide, and condensing them by passing the metallic vapors and the carbon monoxide into a bath of the same metal that is being condensed, which bath is maintained in a molten state, but not much above melting-point, condensing the metal in said bath and passing the carbonic acid through the same.

2. The process of smelting compounds of volatile metals such as described, which consists in heating the finely-divided ore with finely-divided carbon out of contact of air or free oxygen, reducing and vaporizing the metal, and passing the vapors through or among carbon at a still higher temperature and from there to a bath of the same metal which is being condensed, but in a molten condition, and condensing the metallic vapors in said bath.

3. The process of smelting compounds of volatile metals such as described, which consists in heating carbon and the ore together out of contact of free oxygen, distilling off the metal and passing the same together with such carbonic acid and nitrogen as are present with it but without free oxygen or carbonic acid into a bath of the same metal in the molten state, substantially as described, whereby the metal is condensed and the carbon monoxide and nitrogen escape through the bath.

4. The process of smelting compounds of volatile metals such as described, which consists in reducing the ore to a finely-divided state, mixing the same with finely-divided fuel and submitting it to the requisite heat in an atmosphere of carbon monoxide in which no free oxygen or carbonic acid is present, distilling off the volatile metal still surrounded by an atmosphere of carbon monoxide and condensing the metal in a bath of the same metal in a liquid state, and tapping off the less volatile metals.

5. The improvement in the process of smelting compounds of volatile metals, such as described, which consists in bringing them into the vapor state out of presence of oxygen or carbonic acid and passing the vapors through a bath of the same metal in a liquid state at a little above its fusing-point, whereby the metal is condensed and any residual gas that may be present passes through the bath and liquid metal, and escapes.

701,459. PASSENGER OR GOODS ELEVATOR OR CONVEYER. WILLIAM H. ARNOLD, London, England. Filed June 2, 1901. Serial No. 30,344. (No model.)

Claim.—1. In an elevator, the combination with the track, of a movable platform, comprising an endless driving-chain, located centrally of said platform, and provided with links connected by horizontal and vertical pivots, to permit said chain to bend vertically and also laterally, and transverse bars secured to the chain-links, and provided at opposite ends with supporting-rollers engaging said track, and driving mechanism for said chain, substantially as described.

2. The combination with the endless curved track, of an endless platform, comprising an endless driving-chain, a series of horizontally-disposed bars, secured to the links of said chain, supporting-rollers at each end of said bars, for engaging horizontal portions of the track and horizontally-disposed guide-rollers secured to said bars and adapted to engage vertical portions of the track and driving mechanism for said chain, substantially as described.

3. The combination with an endless curved track, of an endless platform, comprising an endless chain, a series of transverse bars, secured thereto, said bars being wider at one end than at the other, supporting-rollers secured to the ends of said bars, and engaging horizontally-disposed portions of the track and horizontal rollers secured to the ends of said bars, and engaging vertical portions of said track and driving mechanism for said chain, substantially as described.

4. In an elevator, the combination with the spiral track, of an endless platform comprising an endless driving-chain located centrally of said platform, transverse bars secured to the links of said chain, certain of said chain-links being provided with vertically-disposed pivots, a supporting-

roller secured to each end of said cross-bars and engaging said track, and horizontal guide-rollers secured to the ends of said transverse bars and engaging vertical portions of said track and driving mechanism engaging said chain, substantially as described.

5. In an elevator, the combination with the spiral track, of an endless platform comprising a driving-chain located centrally of the platform and provided with links connected by horizontal pivots, certain of said links being jointed vertically and connected by vertical pivots, cross-bars secured to said links, each provided with a supporting-roller at each end and engaging the track, said cross-bars being wider at one end than at the other, and a horizontally-disposed roller secured to each cross-bar and engaging a vertical flange of said track and driving mechanism engaging said chain, substantially as described.

6. In an elevator, the combination with the supporting-frame of the spiral track, an endless drive-chain, an endless platform carried by said chain and engaging said track, a series of driving-wheels located at different elevations along said track and engaging said chain, a vertical driving-shaft and connections between said vertical driving-shaft and each of said driving-wheels, for driving said chain simultaneously at different points throughout its length, substantially as described.

7. The combination with the spiral track, provided with sides, of the endless driving-chain, an endless platform carried by said chain and engaging said track, an endless hand-rail engaging the upper edge of one of said sides, and provided with driving projections on its lower flange, a series of drive-wheels engaging said chain at intervals throughout its length, and provided with horizontal shafts, a driving-wheel engaging said hand-rail adjacent to each of said chain-driving wheels, and connected with the shaft thereof, a main driving-shaft extending vertically up through said spiral track and connections from said driving-shaft to each of the shafts of the chain-driving wheels for driving said chain and hand-rail simultaneously at different points throughout their length, substantially as described.

8. In an elevator, the combination with a spiral track having a spirally-arranged ascending portion and a descending portion lying directly beneath and parallel to said ascending portion, an endless platform engaging said track and means for driving said platform, substantially as described.

701,460. SIGNAL. JAMES R. BAKER, Boston, Mass. Filed Nov. 18, 1901. Serial No. 31,700. (No model.)

Claim.—1. A signal comprising a translucent body and a relatively movable signal device, thereabout, substantially as described.

2. A signal comprising a translucent body, a signal device thereabout and means for moving it into a posterior position, in which it is practically invisible, and into an anterior position in which it is visible through the translucent body, substantially as described.

3. A signal comprising a translucent plate and signal-disk thereabout, movable away from and nearly or quite into contact with the plate, to render the disk invisible and visible in turn, substantially as described.

4. A signal comprising a translucent body, a signal device thereabout and electromagnetic actuating means for moving the signal device toward and from the translucent body, substantially as described.

5. A signal comprising a translucent body, an electromagnet fixedly mounted at its back, an armature actuated thereby, a signal device placed behind the translucent body and an axial rod connecting it to the armature to be moved thereby, substantially as described.

6. A signal comprising a translucent body, an electromagnet fixedly mounted at its back and having a pole-piece or pole-pieces outside its coil, an armature cooperating therewith, a signal device placed behind the translucent body and a connection between the armature and signal device to move the latter with relation to the translucent body, substantially as described.

7. A signal comprising a translucent body, an electromagnet fixedly mounted at its back and having a pole-piece or pole-pieces outside its coil, an armature cooperating therewith, a signal device placed behind the translucent body and an axial connection between the armature and signal device to move the latter with relation to the translucent body, substantially as described.

8. A signal comprising a translucent body having a masked and an active portion and a relatively movable signal device behind the active portion, substantially as described.

701,461. SPRING-CUSHION AND ITS SUPPORT. WILLIAM H. BAKER, Jackson, Mich. Filed Nov. 11, 1901. Serial No. 31,708. (No model.)

Claim.—1. The combination with support-wires having straight middle portions, of corrugated wires crossing the same at right angles, and firmly joined thereto at their points of crossing, and conical, convolute springs having their lowermost coils in spring contact with, and on the under side of, outwardly-directed heads of said corrugated wire, and the ends of said springs turned inwardly diametrically of said coils, and in a plane below the same, and formed into a compound curve, with the upwardly-directed head in spring contact with, and on the upper side of a downwardly-directed head of said corrugated wire intermediate the corrugations engaged by said lowermost coils.

2. The combination with support-wires having straight middle portions, corrugated wires crossing the same, sheet-metal hoops having a middle portion rounded to form a seat for said support-wires, and its ends bent at an angle to conform to the angle of the head of the corrugated wire, and folded thereabout on either side of the point of crossing; double conical convolute springs, and single conical convolute springs having the lowermost ends thereof formed into a compound curve diametrically of, and in a plane below the lowermost coils thereof, to hold the spring upon the corrugated wire by the tension and recoil after firing said end over the corrugated wire, with the lowermost coil in contact with the opposite side thereof; and wire-clips to hold the upper ends of the single springs to the double springs, formed of a substantially straight middle portion, with double loops at each end, one set to hold the double spring, and the other to hold the end of the single spring firmly in contact therewith.

3. The combination with a seat-frame, of support-wires having straight middle portions and upward at the ends for fastening the same to the said frame; corrugated cross-wires joined thereto at their points of crossing;

spring formed at their lower ends into a compound curve to facilitate the forcing of said end over the corrugated wire, and also to form a seat to rest upon said corrugated wire to prevent the spring slipping therefrom, the spring being held firmly thereon by the recoil of the said spring at its lower end; a wire 23 to form a spring edge at the upper portions of said springs, and wire-clips having a straight middle portion in contact with the upper coils of said springs, and a double loop at each end to hold the said wire 23 firmly in contact with said top coils of said springs.

4. In a spring-seat, the combination with suitably-supported rows of single springs, of a tie-wire 22 adjacent to the uppermost coils of said spring, having a straight portion contiguous to said springs, and bent to connect with alternate rows, as shown, and wire-clips joining the straight portions of said tie-wire to the uppermost coils of said springs, each of said clips having a comparatively straight middle portion, a loop at each end coiled about the uppermost coil of said spring, and a second loop at each end adjacent to said first loops coiled about the said wire, and holding said tie-wire firmly against said spring, substantially as shown.

5. As a new article of manufacture, a wire-clip for springwork, having a straight middle portion, a loop at each end coiled about one wire, and a second loop at each end coiled about another wire, to connect said wires together.

6. As a new article of manufacture, a wire-clip for connecting a straight wire to a curved wire, consisting of a straight middle portion; a loop at each end coiled about said curved wire and a second loop at each end coiled about said straight wire, clamping the said two wires together.

7. As a new article of manufacture, a wire-clip for joining springs together, or to stay or tie wires, consisting of a comparatively straight portion in contact with said spring; a portion coiled about said spring on either side of said middle portion; a second portion coiled about the other spring or wire which it is desired to be attached to said first spring.

8. As a new article of manufacture, a wire-clip for springwork consisting of a comparatively straight middle portion 19 in contact with a spring; a coil on either side of said middle portion joining said middle portion to said spring; and a second coil on either side of said middle portion joining a second wire to said middle portion, and also to said spring.

9. As a new article of manufacture, a wire-clip for springwork, consisting of a straight middle portion 18, a loop 19, at either end at right angles to said middle portion, for engaging a spring; and a second loop 20, at each end of said clip, and at right angles to said middle portion, for engaging another wire which is desired to be attached to said spring.

701,462. WRENCH. CHARLES F. RUTLAND and SAMUEL TALKINGTON, New Albany, Ind. Filed Dec. 18, 1901. Serial No. 94,423. (No model.)

Claim.—A wrench comprising a bar or lever provided at one end with a jaw having a smooth face of one side for engaging new nuts and provided at the opposite side with a toothed face for engaging worn nuts, and the tapering approximately oval-shaped jaw having a nut-receiving opening and bifurcated at its apex or pointed end to receive the lever or bar and pivoted to the same beyond the jaw thereof, the bifurcation being of sufficient length to permit the jaw to swing beyond the nut-receiving opening at either side to enable it to present either face to a nut without separating and rearranging the parts, substantially as described.

701,463. SOAP ARTICLE. HENRY L. BOWELL, Cleveland, Ohio, assignor of one-eighth to Fred Wells, Chicago, Ill. Filed May 16, 1901. Serial No. 94,499. (No model.)

Claim.—1. A soap-retainer comprising, a body portion web-shaped and designed to extend centrally through the ends of soap, in combination with diagonally-placed flanges thereon so arranged upon the web as to form grooves therewith, adapted to be engaged by the fingers of either hand when the soap is nearly exhausted therefrom, substantially as described.

2. A soap-retainer comprising, a body portion of thin web-shaped material, in combination with diagonally-placed flanges thereon, the flanges on one side being placed at an angle to the flanges on the other side, as for the purpose set forth.

3. A soap-retainer, comprising, a webbed central portion and later-

gral projecting perforated handle portion, in combination with diagonal flanges forming grooves with the body portion, as and for the purpose described.

701,464. WATER-COOLING APPARATUS FOR MOTOR-VEHICLES. EDWARD T. BROWDER, Portland, Me. Filed May 7, 1901. Serial No. 94,114. (No model.)

Claim.—1. In a motor-vehicle, the combination with a body and motor carried thereby, of a water-cooler mounted upon the vehicle and having an open-ended cooling-space into which the water is discharged and having an open-ended cooling-space into which the water is discharged, a series of baffles in said space over which the water passes while directly exposed to air-currents created by the movement of the vehicle, and means for circulating the water, substantially as described.

2. In a motor-vehicle, the combination with a body and motor carried thereby, of a water-cooler mounted upon the vehicle having an open-ended cooling-space into which the water is discharged, a series of baffles in said space over which the water passes while directly exposed to air-currents created by the movement of the vehicle, and means for circulating the water to and from the motor-jacket, substantially as described.

3. In a motor-vehicle, the combination with a body and motor carried thereby, of a water-cooler mounted upon the vehicle and having an open-ended cooling-space into which the water is discharged, baffles in said space over which the water may pass while directly exposed to air-currents created by the movement of the vehicle, means for preventing the water from flowing out of the end of the cooling-space, and means for circulating the water, substantially as described.

4. In a motor-vehicle, the combination with a body and motor carried thereby, of a circulating system in communication with the motor adapted to contain a cooling medium for said motor, said system having an opening through which the cooling medium may be directly exposed to air-currents created by the movement of the vehicle, substantially as described.

701,465. MIXING-MACHINE FOR CONCRETE. DR. WILLIAM R. GAY, Philadelphia, Pa. Filed Mar. 4, 1902. Serial No. 97,815. (No model.)

Claim.—1. In a mixing-machine, the combination of a cylindrical casing of greater height than width having a hopper at its top and opening into it at one end and having a discharge-opening at its bottom at the other end, a rotating shaft extending longitudinally through the casing and carrying spirally-arranged mixing-blades to sweep the interior and lower portion of the casing but clear the surface of the upper portion, and a water-spraying pipe arranged in the upper part of the casing for spraying water upon the material being mixed.

2. In a mixing-machine, the combination of a cylindrical casing hav-

ing a hopper at its top and opening into it at one end and having a discharge-opening at its bottom at the other end, a rotating shaft extending longitudinally through the casing and carrying spirally-arranged mixing-blades to sweep the interior and lower portion of the casing, and a water-spraying pipe arranged in the upper part of the casing and across the throat or opening of the hopper into the casing for spraying water upon the material being delivered to the casing and mixing-blades to be mixed.

3. In a mixing-machine, the combination of a cylindrical casing having a hopper at its top and opening into it at one end and having a discharge-opening at its bottom at the other end, a rotating shaft extending longitudinally through the casing and carrying spirally-arranged mixing-blades to sweep the interior and lower portion of the casing, and a water-spraying pipe arranged in the upper part of the casing across the throat of the hopper and over the casing beyond the throat for spraying water upon the material as they enter the casing and also as they are being mixed.

4. In a mixing-machine, the combination of a cylindrical casing of greater height than width having a hopper at its top and opening into it at the highest end and having a discharge-opening at its bottom at the other end and arranged on an incline, a rotating shaft extending longitudinally through the casing and carrying spirally-arranged mixing-blades to sweep the interior and lower portion of the casing and a water-spraying pipe arranged in the upper part of the casing across the throat of the hopper for spraying water upon the material being mixed.

5. In a mixing-machine, the combination of a cylindrical casing having a hopper at its top and opening into it at one end and having a discharge-opening at its bottom at the other end, a rotating shaft extending longitudinally through the casing and carrying spirally-arranged mixing-blades to sweep the interior and lower portion of the casing and in which the obliquity of the blades is greater at the discharging end than at the hopper end, and a water-spraying pipe arranged in the upper part of the casing for spraying water upon the material being mixed.

6. In a mixing-machine, the combination of a cylindrical casing having a hopper at its top and opening into it at one end and having a discharge-opening at its bottom at the other end, a rotating shaft extending longitudinally through the casing and carrying spirally-arranged mixing-blades to sweep the interior and lower portion of the casing and in which the obliquity of the blades is greater at the discharging end than at the hopper end.

7. In a mixing-machine, the combination of a cylindrical casing of greater height than width having a hopper at its top and opening into it at one end and having a discharge-opening at its bottom at the other end, a rotating shaft extending longitudinally through the casing and carrying spirally-arranged mixing-blades to sweep the interior and lower portion of the casing and in which the obliquity of the blades is greater at the discharging end than at the hopper end, and a water-spraying pipe arranged in the upper part of the casing for spraying water upon the material being mixed.

8. In a mixing-machine, the combination of a cylindrical casing of greater height than width having a hopper at its top and opening into it at one end and having a discharge-opening at its bottom at the other end, a rotating shaft extending longitudinally through the casing and carrying spirally-arranged mixing-blades to sweep the interior and lower portion of the casing and in which the obliquity of the blades is greater at the discharging end than at the hopper end, and a water-spraying pipe arranged in the upper part of the casing for spraying water upon the material being mixed.

9. In a mixing-machine, the combination of a cylindrical casing of greater height than width having a hopper at its top and opening into it at one end and having a discharge-opening at its bottom at the other end and an opening at its top intermediate of the hopper and discharge end, a door or cover for said opening, a rotating shaft extending longitudinally through the casing and carrying spirally-arranged mixing-blades to sweep the interior and lower portion of the casing and a water-spraying pipe arranged in the upper part of the casing for spraying water upon the material being mixed.

701,466. CENTRIFUGAL FILLING-MACHINE. NORMAN C. FOX, Vienna, Austria-Hungary. Filed Dec. 4, 1900. Serial No. 94,994. (No model.)

Claim.—1. In a machine such as described, the combination with a centrifugal drum, of a ring of interlocked carriers each carrying a multiplicity of open-ended tubular holders for the reception of tubes to be filled, a feed-nozzle at the inner end of each holder and means for removably locking said ring of carriers to the inner periphery of the drum, for the purpose set forth.

2. In a machine such as described, the combination with a centrifugal drum, of a ring of interlocked carriers each carrying a multiplicity of removable open-ended tubular holders for the reception of tubes to be filled, a feed-nozzle at the inner end of each holder and means for removably locking said ring of carriers to the inner periphery of the drum, for the purpose set forth.

3. In a machine such as described, the combination with a centrifugal drum, of a ring of carriers each provided with a multiplicity of bearings, a tubular open-ended holder for the reception of a tube to be filled, removable from and reversible in each of said bearings, means for revolving the tube-holder, a feed-nozzle at the inner end of said holder and means for removably locking the said ring of carriers to the inner periphery of the drum, for the purpose set forth.

4. In a machine such as described, the combination with a centrifugal drum, of a ring of carriers each provided with a multiplicity of bearings, a tubular open-ended holder for the reception of a tube to be filled, removable from and reversible in each of said bearings, means for simultaneously revolving the tube-holder, a feed-nozzle at the inner end of said holder, and means for removably locking the said ring of carriers to the inner periphery of the drum, for the purpose set forth.

5. In a machine such as described, the combination with a centrifugal drum, of a ring of interlocked carriers bodily removable from said drum, each carrier carrying a multiplicity of open-ended tubular holders for the reception of tubes to be filled, a feed-nozzle at the inner end of each tube, means for removably locking the ring of carriers to the inner periphery of the drum, and means for connecting the ring of carriers to a hoisting-latch, for the purpose set forth.

6. In a machine such as described, the combination with a centrifugal drum, of a ring of interlocked carriers each carrying a multiplicity of open-ended removable tubular holders for the reception of tubes to be filled, a feed-nozzle at the inner end of each holder, said ring of carriers adapted to be bodily moved out of and into said drum, means for guiding the ring of carriers when so moved and locking it against rotary motion independently of the drum, and means for holding said ring of carriers against vertical displacement, for the purpose set forth.

7. In a machine such as described, the combination with a centrifugal drum, of a circular frame comprising a bottom plate and spacers radiating laterally from the periphery thereof and dividing the same into rectangular spaces, a carrier for and fitting into each of said spaces and carrying a multiplicity of open-ended removable tubular holders for the reception of the tubes to be filled, a feed-nozzle at the inner end of each holder, means for locking the carriers against radial displacement, a top ring secured to the spacers and holding the carriers against vertical displacement, and means for locking the ring of carriers thus formed against rotary motion independently of the drum, for the purpose set forth.

8. In a machine such as described, the combination with a centrifugal drum, of a disk fitting into the drum, spacers radiating laterally from the periphery of said disk and dividing the same into rectangular spaces, carriers fitting into said spaces and carrying each a multiplicity of removable open-ended tubular holders for the reception of tubes to be filled, a feed-pipe on the inner face of each carrier, provided with a feed-nozzle

for each of the holders, a locking-bar removably secured to the spacers and lapping over adjacent carriers, a top ring for holding the carriers against vertical displacement bolted to the spacers, the latter provided with a ring at their upper end and above the top ring, means removably locking the ring of carriers thus formed to the inner periphery of the drum, means for holding the carriers against outward radial movement and a retaining-ring for holding the ring of carriers against vertical motion in the drum, for the purposes set forth.

701,467. WIRE-NAIL MACHINE. JAMES H. CLARK and ALFRED HAYES, Philadelphia, Pa. Filed June 1, 1901. Serial No. 62,792. (No model.)

Claim.—1. In combination with a machine of the character described, a framework, a main shaft journaled in suitable bearings upon said framework, a point-forming die composed of two members pivotally connected, a cam secured to the main shaft adapted to open and close the said point-forming die through the medium of a system of levers, a grasping and head-forming die composed of two members pivotally connected together, a cam secured to the main shaft for the purpose of opening and closing said die through a system of levers, a cam secured to the main shaft adapted to move the point-forming die through a system of levers longitudinally toward and away from the head-forming die, two plungers adapted to move toward and away from the string of nails, a cam located upon the main shaft and adapted, through the medium of the system of levers, to force said plungers toward the string of nails, a spring adapted to return said plungers to their original position at the proper time, dies secured to the inner ends of said plungers, the contour of each of said dies being of the shape of the desired form of nail, the said dies, when the plungers are forced inward, adapted to grasp the nail below the fin which is to be trimmed off, a plunger adapted to reciprocate vertically in suitable guideways, said plunger adapted to be forced downward and engage the Shank of two nails upon each side of the head and point for the purpose of forcing the string of nails a slight distance downward between the dies, a cam secured to the main shaft and adapted to force the plunger downward through the medium of the system of levers, a spring for the purpose of returning the plunger to its original position at the proper time, a bell-crank lever pivoted to the main frame of the machine, a guide through which the string of nails passes formed with or secured to the end of the horizontal member of the bell-crank lever, a roller journaled in the lower end of the vertical member of the bell-crank lever, a cam secured to and adapted to revolve with the main shaft of the machine and operate against said roller for the purpose of raising the string of nails at the proper time, a spring for returning the lever to its normal position, a re-

tary feeding mechanism consisting of two spur-wheels arranged one above the other and in mesh with each other, suitable standards in which said spur-wheels are journaled, means for communicating motion to the lower spur-wheel, sliding blocks in which the upper spur-wheel is adapted to be journaled, said blocks adapted to slide in suitable guideways in the standards, springs arranged above said blocks and adapted to exert pressure downward upon the same, adjusting devices arranged above said springs for the purpose of adjusting the tension of the same, an annular grooved disk secured to the face of the lower spur-wheel, a block secured to the one face of the upper spur-wheel, a surface carried by said block adapted to contact the wire upon every revolution of the spur-wheel for the purpose of feeding the same forward, frictional cones arranged in front of the feeding mechanism adapted to exert pressure upon each side of the wire at all times, a reel upon which the string of nails is adapted to be wound, a guide-roll through which the string of nails is guided from the feeding device of the reel, a guide-roll pivoted to spring-actuating lever for the purpose of taking up the slack in the string of nails as the same is fed forward, means independent upon the revolution of the reel for sliding the guideways backward and forward the width of the reel for the purpose of evenly winding the string of nails, a friction-roll adapted to bear against one side of the reel for the purpose of revolving the same, movement communicated to the said friction-roll from the main shaft, means dependent upon the revolution of the reel for moving the friction-roll gradually toward the periphery of the reel, substantially as described and for the purpose specified.

2. In combination with a machine of the character described, a suitable framework, a main shaft journaled in suitable bearings upon said framework, a point-forming die composed of two members pivotally connected together, one member being adapted to slide longitudinally of the machine in suitable guideways, the other member adapted to rock upon a pivot for the purpose of opening and closing the die and adapted to slide longitudinally with the other member, toggle-joint interposed between the rear ends of the two members, a pivoted lever adapted to operate upon said toggle-joint for the purpose of opening and closing the jaws of the die, a cam secured to the main shaft for the purpose of rocking said lever, a grasping and head-forming die composed of two members, said members connected together by a pivot, said pivot having a bearing upon the main shaft of the machine, a toggle-joint being interposed between the two ends of said members, a lever pivoted to the main frame of the machine adapted to operate upon said toggle-joint when said lever is rocked for the purpose of opening and closing the jaws of the head-forming die, a cam secured to the main shaft of the machine for the purpose of engaging said lever and rocking the same, a toggle-joint interposed between the rear end of the point-forming die, and a stationary standard secured to the head-plate of the machine, levers adapted to operate upon said toggle-joint for the purpose of forcing the point-forming die toward and away from the head-forming die, a cam secured to the main shaft of the machine adapted to operate upon said levers, means for trimming the waste material from the nail after passing from the dies, means for feeding the string of nails forward a predetermined distance, means for guiding and reeling said string of nails into a coil, substantially as described and for the purpose specified.

3. In combination with a machine of the character described, point-forming die composed of two members pivotally connected together, said dies adapted to open vertically, head-forming die composed of two members pivotally connected together and adapted to open vertically, one member secured to the main shaft of the machine adapted to actuate mechanism for opening and closing both of said dies, a cam secured to the main shaft of the machine and adapted to actuate mechanism to cause the point-forming die to be forced toward and away from the head-forming die, the cam-carriage upon all of the said cams being formed in such a manner that the longitudinally-sliding point-forming die will move backward and forward twice in the formation of the head of the nail, the head-forming die opening and closing at the proper intervals to permit this movement, the point-forming die remaining closed until the head is formed, substantially as described and for the purpose specified.

4. In combination in a machine of the character described, nail-forming die with trimming mechanism consisting of two horizontal plungers, each of said plungers having secured upon its inner end a die, each of said dies having a contour of the shape of one-half of the head and point of the nail where they are joined together, said plungers and dies adapted to reciprocate toward and away from one another transversely to the line of travel of the nails, suitable bearings for guiding said plungers, a system of levers for forcing said plungers toward one another, a cam secured to the main shaft of the machine adapted to operate upon said system of levers for forcing the said plungers toward at the proper time, a spring adapted to operate to force said plungers apart at the proper time, said plungers when brought together adapted to grasp the string of nails below the position to be trimmed off, a vertical plunger arranged above the point where the two horizontal plungers grasp the string of

nails, said plunger adapted to be reciprocated vertically in suitable bearings, the end of said plunger being so formed that when it is forced downward it will engage the Shank of the nails upon each side of the head and point and press the mid string of nails downward between the dies, a system of levers for communicating motion to the vertically-reciprocating plunger, a cam secured to the main shaft of the machine for operating upon said system of levers for forcing the vertical plunger downward, a spring adapted to operate upon said system of levers and permitted to do so by the cam for the purpose of raising and holding said vertical plunger in its upper or normal position, substantially as described and for the purpose specified.

5. In a machine of the character described, the combination of nail-forming die, trimming and feeding mechanism with reeling mechanism consisting of a reel mounted upon a shaft journaled in suitable bearings, said reel adapted to be driven by a friction-roller bearing against one side of said reel, a spring interposed between the hub of said reel and a collar upon its shaft for the purpose of keeping said reel in contact with the friction-roller, said friction-roller being mounted upon a shaft which is journaled in bearings secured to a longitudinally-sliding plate, motion being communicated to the friction-roller through a pulley also mounted in bearings secured to said sliding plate, said pulley receiving its motion through a belt which passes over said pulley and also around a stationary drum, which drum receives its motion from the main shaft of the machine, a worm mounted upon the reel-shaft and adapted to revolve, a worm-wheel mounted upon a vertical shaft, a cam-wheel also mounted upon said vertical shaft and adapted to be revolved by the worm-wheel, a lever, one end being pivoted to the main frame of the machine, the other end adapted to lie in contact with said cam-wheel, a pawl pivoted to said lever and adapted to engage ratchet-teeth formed in an extension connected to the longitudinally-sliding plate for the purpose of sliding said plate rearward a slight distance whenever said lever is rocked by the said cam-wheel, a spring for returning said lever to its normal position when permitted to do so by the cam, guide-rollers through which the string of nails is adapted to be guided, means controlled by the revolution of the reel for sliding said guide-rollers laterally backward and forward a distance equal to the distance of the coil to be formed for the purpose of evenly winding the said coil, substantially as described and for the purpose specified.

6. In combination with a machine of the character described, a reel adapted to be revolved at a decreasing rate of speed as the coil wound thereon enlarges, a pair of guide-rollers between which the string of nails is guided, said guide-rolls being journaled in suitable bearings formed with or secured to a lateral sliding block, suitable guideways for guiding said block, a supplemental pair of guide-rolls between which the string of nails also passes and is guided, said guide-rolls being journaled in the forward end of a lever pivoted to the sliding block, a spring arranged to exert pressure upward upon said lever for the purpose of taking up the slack in the string of nails when the said string is fed forward, a link pivoted to the sliding block at one end, the other end of said link being pivoted to a lever which is in turn mounted upon a vertical shaft, a lever also secured to the vertical shaft and having a roller at its outer end adapted to bear against the periphery of a cam-wheel, said cam-wheel adapted to be revolved through suitable mechanism connected with the reel-shaft, said cam adapted to force the sliding block and guide-rolls gradually toward one side of the reel, a spring adapted to return the sliding block and guide-rolls to the other side of the reel for the purpose of evenly winding the coil, substantially as described and for the purpose specified.

7. In combination with a machine of the character described, a reel consisting of one member having a drum formed thereon, said member adapted to be driven through power being communicated to it through the main shaft of the machine, a second member consisting of a disk adapted to be removably secured to the reel-shaft, a pin secured in the removable member and adapted to register with and enter a hole formed in the permanent member, a plurality of discs formed through both members and extending from the drum outward to the periphery for the purpose of binding the coil with wire or the like while the same is upon the reel, fingers pivoted to the permanent member of the reel and adapted to lie within the slots in said member and be flush with the inner face of the reel when the coil is being formed, said fingers adapted to be swung outward and held in that position as to leave the slots accessible for the binding of the coil, substantially as described and for the purpose specified.

701,468. STOVEPIPE. ALBERT CLARKIN, Milwaukee, Wis. Filed Jan. 12, 1902. Serial No. 30,608. (No model.)

Claim.—1. A pipe-section provided at its edges with interlocking hook-shaped flanges, one edge being without any flange at one end and the opposed portion of the pipe being provided with a pocket having an inclined bottom for receiving the said blank portion of the opposed edge

and permitting the said hook-shaped flanges to be interlocked without longitudinal movement, substantially as set forth.

2. A pipe-section provided at its edges with interlocking hook-shaped flanges and provided also upon one edge with an offset portion extending longitudinally behind one of the said flanges, one edge of the said pipe being without any flange at one end and the opposed portion of the pipe being provided with a pocket having an inclined bottom for receiving the said blank portion of the opposed edge, substantially as set forth.

3. A pipe-section provided at its edges with interlocking hook-shaped flanges *c* and an offset portion *b* extending longitudinally behind the flange *c*, one edge being without the said flange *c* at one end and the opposed edge being provided with a pocket *f* having an inclined bottom *f'* for engaging with the said blank portion of the pipe, said pocket *f* being formed between two folds of the metal and upon the inside of the pipe, substantially as set forth.

701,469. RAILWAY OR TRAMWAY VEHICLE. DAVID D. COATE, Bangon, India. Filed Mar. 6, 1901. Serial No. 50,096. (No model.)

Claim.—In connection with a railway or similar vehicle, a two-wheeled truck, consisting of the two wheels each having an outer flange and with its main portion increasing in diameter inward from said flange, the axle-carrying said wheels and extended beyond the same to provide an outer spindle at each end, a journal-box with superposed one-spring upon each spindle, a truck-frame carried by said journal-boxes and springs, and a 60th-wheel and king-bolt in said truck-frame, upon and by which the vehicle-body is attached to said truck, said 60th-wheel and king-bolt being directly above the geometric center of said axle, substantially as and for the purpose described.

701,470. VEHICLE-POLE. GEORGE W. CONRAD, Troy, Ohio, assignor to the Troy Spring Company, Troy, Ohio. Filed Feb. 12, 1902. Serial No. 32,517. (No model.)

Claim.—1. In a vehicle-pole, a pole proper having a single bend at its rearward end and in combination with a double-head circle or bow, substantially as and for the purpose specified.

2. In a vehicle-pole, a single-bend pole in combination with a double-head circle or bow, and braces connecting the sides of the circle or

bow with the pole, said braces occupying straight lines and imparting suitable strength to the bow or circle, substantially as specified.

701,471. BENCH-PLANE GUIDE. GEORGE S. DUNN, Manchester, N. H., assignor of one-half to George A. Dunbar, Manchester, N. H. Filed Sept. 9, 1901. Serial No. 74,761. (No model.)

Claim.—A guide for flanged bench-planes consisting of a frame having at one end an extension terminating in an integral hook to engage the flange, an extension at the other end of the frame, a cone pivoted on the latter extension adapted to clamp the body of the plane, ears on the frame, a guide-plate pivoted to the ears, a pivoted arm on the guide-plate adjustable in a slot in a lag on the frame, and a set-screw passed through the lag against the arm for maintaining the adjustment.

701,473. APPARATUS FOR COVERING FLEXIBLE CONDUITS WITH RUBBER IN CEMENT OR LIQUID FORM. JOHN T. DORSEY, Hoboken, N. J. Filed June 7, 1901. Serial No. 62,622. (No model.)

Claim.—1. In an apparatus for covering flexible conduits with rubber in cement or liquid form or other similar elastic liquids, a coating-pan consisting of a vessel supported by standards, a guide-roller journaled to arms secured to a rod extending across said vessel, which has one side extending, perforated, a hollow cylinder partially conical, partially straight provided with two slots or eyes, secured over said perforation for the purpose specified.

2. In an apparatus for covering flexible conduits with rubber in cement or liquid form or other similar elastic liquids the combination of a coating-pan, a vessel supported by standards, a guide-roller journaled to arms secured to a rod extending across said vessel, having one side extending, perforated, a hollow cylinder partially conical, partially straight the bearer of two slots or eyes, secured over said perforation, with a spreading device consisting of a tube or pipe partially slit open intersected by a cross-rod, forming two lips, bent to a tube, its diameter regulated by a round clamp and its bolt, said pipe bearing two arms having their ends shaped to a hook, all substantially as set forth.

3. In an apparatus for covering flexible conduits with rubber in cement or liquid form or other similar elastic liquids, a drying-pan consisting of a plate supported by standards, a steam-coil secured to the upper

face of said plate, heated by perforated sheet metal, brackets extending from said plate near longitudinal edges, in which are journaled guide-rollers, a cover having slides on both of its ends, which inclose said apparatus, all substantially as set forth.

4. The combination is an apparatus for covering flexible conduits with rubber in cement or liquid form or other elastic liquids of a drying-pan, its plate supported by standards, a steam-coil secured to upper face of said plate, inclosed by perforated sheet metal, brackets extending from said plate near longitudinal edges in which guide-rollers are journaled, a cover having slides on both of its ends which inclose said apparatus, with an endless belt supported by flanged rollers, journaled to brackets, a driving-pulley secured to shaft of one of said rollers, all substantially as described.

5. In an apparatus for covering flexible conduits with rubber in cement or liquid form or other similar elastic liquids a cleaning-pan consisting of a vessel provided with standards, guide and brush rollers extending across said vessel, the brush-bearing rollers rotated in same direction by means of driving-pulleys secured to their shafts, all substantially as specified.

6. An apparatus for covering flexible conduits with rubber in liquid form or similar elastic liquids consisting of a coating-pan, having a vessel supported by standards, a guide-roller journaled to arms secured to a rod extending across said vessel, having one side extending, perforated, a partially straight, partially conical cylinder fitted to said perforation, two eyes secured to the former; a spreading device consisting of a pipe, partially slit open, intersected by a cross-rod forming two lips, bent to a tube, its diameter regulated by a round clamp and its bolt, the straight portion of the adjustable pipe fitted to the same portion of the stationary, hook-shaped arms extending from the former fitted in the eyes located on the conical portion of the latter; a drying-pan consisting of a plate supported by standards, a steam-coil secured to upper face of said plate, inclosed by perforated sheet metal, brackets extending from former near its longitudinal edges in which guide-rollers are journaled, a cover with slides inclosing said apparatus, an endless belt supported by rollers and its standards guiding the material already coated through the drying-pan; a cleaning-pan consisting of a vessel, its standards, guide-rollers and brush-rollers extending across said vessel the latter rotating in same direction by means of driving-pulleys, flanged rollers placed one in front of the coating-pan and one in the rear of the cleaning-pan, for supporting the conduit before and after the operation, and pulleys secured to the shafts thereof, substantially as described.

701,478. MACHINE FOR KNEADING AND WASHING MARBLE OR OTHER SIMILAR SUBSTANCES. LOUIS B. DORRIS, Antwerp, Belgium. Filed Sept. 4, 1901. Serial No. 74,962. (No model.)

Claim.—The combination of a substantially cylindrical receptacle having an opening in its side wall, a supporting-frame, said receptacle being arranged to turn in said frame, a shaft arranged parallel with said receptacle, reversely-rotatable cages arranged in said receptacle, means for rotating one of said cages, gearing connecting said shaft with the other cage, and disconnection means for turning said receptacle in the frame, a portion of said means being carried by said shaft, substantially as described.

701,474. HOT-BLAST FOR RANGES OR COOKING-STOVES. JOHN A. BURLIN, Indianapolis, Ind. Filed Feb. 17, 1902. Serial No. 94,694. (No model.)

Claim.—1. In a hot-blast for ranges and cooking-stoves, a discharge-pipe substantially as shown, the said pipe being conical in form and terminating at one end in an integrally-formed ingrain-bowl, slots in the pipe which form an airtight seal for the air, a plate 6 forming the top for the discharge-pipe, bolts passing through the top plate and the pipe by which the parts are secured together, integral flanges on the pipe and bowl which carry apertures, bolts passing through the said apertures in the flanges and the range top and back, whereby a means is provided for securing the hot-blast to the range or stove, substantially as shown and described.

2. In a hot-blast for ranges and cooking-stoves, a discharge-pipe substantially as shown, the said pipe being conical in form and flaring in a horizontal direction, slots in the pipe which form an airtight seal for the air, the discharge-pipe extending through and is secured to the back of the range or stove by means of the flange 16 and the bolts 17, the discharge-pipe curving upward at its rear end and terminating in an integrally-formed ingrain-bowl, the upper edge of the bowl registering with an aperture in the range-top, flanges on the bowl which carry apertures for the bolts 18, similar integral flanges within the ingrain-bowl which form a seat for the damper-plate 9, a damper composed of the plate 8 and 9, the plate 9 of the damper being adjustably secured in the plate 8, the combined plates forming a means for regulating the inflow of air, substantially as shown and for the purposes set forth.

3. In a hot-blast for ranges and cooking-stoves, a discharge-pipe conical in form, the said pipe extending into the fire-box of the range or stove, the rear end of the pipe being curved upward and terminating in an ingrain-bowl, integral flanges on said bowl which carry apertures, bolts extending through the said apertures and the range-top, whereby the parts are secured together, a secondary ornamental stand secured to the upper surface of the range which forms the ingrain for the hot-blast, ears integrally formed on the said stand, the front ears of which form a bearing for the swinging handle while the rear ears form a bearing for the ornamental back, substantially as shown and for the purposes set forth.

701,475. VAPOR-STOVE. JAMES H. FINE, KANSAS CITY, Mo., and RAYMOND ANDERSON, KANSAS CITY, Mo. Filed Mar. 11, 1901. Serial No. 20,024. (No model.)

Claim.—1. In a vapor-stove, the combination with a generator, of a waste-receptacle, means for conveying liquid oil emitted by the generator into the waste-receptacle, an oil-supply tank located normally higher than the generator and the waste-receptacle, but adapted to be disposed in a position lower than the waste-receptacle and the generator, an oil-conductor provided with an always-open passage connecting the supply-tank with the generator, an oil-conductor provided with a passage connecting the waste-receptacle with the supply-tank, and having means for closing the latter passage when the supply-tank is in the raised position, substantially as described.

2. In a vapor-stove, the combination with a generator, of a waste-receptacle, means for conveying liquid oil emitted by the generator into the waste-receptacle, an oil-supply tank located normally higher than the generator and the waste-receptacle, but adapted to be disposed in a position lower than the waste-receptacle and the generator, an oil-conductor provided with an always-open passage connecting the supply-tank with the generator, an oil-conductor provided with a passage connecting the waste-receptacle with the supply-tank and having a valve for closing the latter passage when the supply-tank is in the raised position, substantially as described.

3. In a vapor-stove, the combination with a generator, of a waste-receptacle, a burner disposed intermediate the generator and the waste-receptacle in a position adjacent to the generator, means for conducting the liquid oil emitted from the generator to the said burner and thence into the waste-receptacle, an oil-supply tank located normally higher than the generator and the waste-receptacle, but adapted to be disposed in a position lower than the generator and the waste-receptacle, an oil-conductor provided with an always-open passage connecting the supply-tank with the generator, an oil-conductor provided with a passage connecting the waste-receptacle with the supply-tank, and having means for closing the latter passage when the supply-tank is in the raised position, substantially as described.

4. In a vapor-stove, the combination with the burner, of a generator, means for mixing air with the vapor emitted from the generator and conducting the mixture to the burner, a waste-receptacle, a supplemental burner intermediate the generator and the waste-receptacle, and means for conveying liquid oil emitted from the generator to the supplemental burner and from thence into the waste-receptacle, substantially as described.

5. In a vapor-stove, the combination with the burner, of a generator, means for mixing air with the vapor emitted from the generator and conducting the mixture to the burner, a waste-receptacle, a supplemental burner intermediate the generator and the waste-receptacle, means for conveying liquid oil emitted from the generator to the supplemental burner and from thence into the waste-receptacle, and a casing enclosing the supplemental burner for conveying heat therefrom to the generator, substantially as described.

6. In a vapor-stove, the combination with a generator, of a burner, means for mixing air with the vapor emitted from the generator and conveying the mixture to the burner, a waste-receptacle, a supply-tank located normally higher but adapted to be disposed in a position lower than the waste-receptacle and the generator, a supplemental burner intermediate the generator and the waste-receptacle, means for conveying liquid oil emitted from the generator to the supplemental burner and from thence into the waste-receptacle, an always-open oil-conductor connecting the supply-tank with the generator, an oil-conductor connecting the waste-receptacle with the supply-tank, and provided with means for closing the latter conductor when the supply-tank is in the raised position, substantially as described.

7. In a vapor-stove, the combination with a generator, of a waste-receptacle, a burner intermediate the generator and the waste-receptacle, means for conveying liquid oil emitted from the generator to the burner and thence into the waste-receptacle, a supply-tank located normally higher than the generator and the waste-receptacle, but adapted to be disposed in a position lower than the waste-receptacle and the generator, a conductor provided with an always-open passage connecting the supply-tank with the generator, a conductor provided with a passage connecting the waste-receptacle with the supply-tank, and having means for closing the latter passage when the supply-tank is in the raised position, substantially as described.

8. In a vapor-stove, the combination with a generator, of a waste-receptacle, a burner intermediate the waste-receptacle and the generator, means for conveying liquid oil emitted from the generator to the burner and thence into the waste-receptacle, a supply-tank located normally higher than the generator and the waste-receptacle, but adapted to be disposed in a position lower than the generator and the waste-receptacle, a casing enclosing the burner for conveying heat to the generator, a conductor provided with a passage connecting the waste-receptacle and the generator with the supply-tank, and having means for closing the passage to the waste-receptacle when the supply-tank is in the raised position, substantially as described.

9. In a vapor-stove, the combination with a generator, of a mixing-chamber for receiving vapor emitted from the generator, a waste-receptacle, a burner disposed intermediate the waste-receptacle and the mixing-chamber, means for conveying liquid oil from the mixing-chamber into the burner and thence into the waste-receptacle, and an inclined conductor for carrying downward liquid oil emitted from the generator into the mixing-chamber, substantially as described.

10. In a vapor-stove, the combination with a generator, of a mixing-chamber for receiving vapor emitted from the generator, a waste-receptacle, a burner located intermediate the waste-receptacle and the mixing-chamber, a casing enclosing the burner for conveying heat therefrom to the generator, an inclined conductor for conveying liquid oil from the generator downward into the mixing-chamber, and means for conveying liquid oil passing into the mixing-chamber to the burner and thence into the waste-receptacle, substantially as described.

11. In a vapor-stove, the combination with a generator, of a burner, means for conveying vapor emitted from the generator to the burner and mixing with air, a waste-receptacle, a supplemental burner disposed between the generator and the waste-receptacle, means for conveying liq-

aid oil omitted from the generator to the supplemental burner and thence into the waste-receptacle, a casing enclosing the supplemental burner for conveying heat therefrom to the generator, and a deflector disposed above the casing in a position such as it will deflect the flame in the casing to the main burner, substantially as described.

12. In a vapor-stove, the combination with a generator, of a waste-receptacle, a burner disposed intermediate the generator and the waste-receptacle, an oil-conductor leading to the waste-receptacle from the burner, a mixing-chamber provided with a lateral opening for receiving air and also for receiving vapor discharged from the generator, and provided with an opening for the discharge of mixed vapor and air, an inclined oil-conductor for conveying oil downward from the generator through the said lateral opening into the mixing-chamber, and a conductor leading from the mixing-chamber to the said burner, substantially as described.

13. In a vapor-stove, the combination with a generator, of a waste-receptacle, a conductor for oil leading to the waste-receptacle, a burner provided with an oil-conveying chamber having an internal oil-passage leading to the said conductor, and having oil-passages leading from the chamber to the exterior of the burner for carrying oil to the outside thereof, and an oil-passage leading from the exterior of the burner into the said waste-receptacle conductor, and means for conveying liquid oil from the generator into the said chamber, substantially as described.

14. In a vapor-stove, the combination with a burner provided with an oil-receiving chamber and having an internal oil-passage leading therefrom and a passage leading to the exterior thereof, and a groove for receiving the oil passing to the exterior of the burner, of an oil-conductor connected to the said groove and the said internal passage, and an oil-conductor leading to the said chamber, substantially as described.

15. In a vapor-stove, a burner comprising a body provided with a chamber having an oil-inlet leading thereon, an internal discharge-passage, passages leading from the chamber to the exterior thereof, a groove in the exterior of the body to receive the oil discharged upon the exterior, and a passage leading from the said groove to the said internal passage, substantially as described.

16. In a vapor-stove, the combination with a supply-tank, of a valve member provided with a tapering bore therethrough and having two openings leading therefrom to the exterior thereof, a rotary member fitted to the said tapering bore and provided with an internal oil-passage always communicating with one of the said openings and communicating with the other opening when the valve member is rotated to a certain position, and a pipe connecting the supply-tank with the said rotary member and communicating interiorly with the tank and the internal oil-passage of the said rotary member, substantially as described.

17. In a vapor-stove, the combination with a generator, of a burner so disposed as to impart heat to the generator and to receive vapor discharged therefrom, a supplemental burner, a waste-receptacle, and means for conducting liquid oil omitted from the generator to the supplemental burner and thence into the waste-receptacle in a continuous flow and without the formation of oil pools, substantially as described.

18. In a vapor-stove, the combination with a generator, of a burner, a waste-receptacle, means for conducting oil to the generator, means for conducting oil from the waste-receptacle to the said oil-conducting means, and means for conducting liquid oil omitted from the generator to the burner and thence into the waste-receptacle in a continuous flow and without the formation of oil pools, substantially as described.

19. In a vapor-stove, the combination with a generator, of a burner so disposed as to impart heat to the generator and to receive vapor discharged therefrom, a supplemental burner, a waste-receptacle, means for conducting oil to the generator, means for conducting oil from the said waste-receptacle to the said oil-conducting means, and means for conducting liquid oil omitted from the generator to the supplemental burner and thence into the waste-receptacle in a continuous flow and without the formation of oil pools, substantially as described.

701,476. EYBLET. JOHN W. PUGH, New Britain, Conn. Filed Dec. 10, 1901. Serial No. 86,570. (No model.)

Claim.—1. An cyclist comprising in its construction, a tubular-shaped body, a flat flange arranged at one end thereof, notches at intervals in said flange forming radial projections, the sides of said projections being downturned and located in radial planes with respect to the axis of the tubular-shaped body, substantially as described.

2. An cyclist comprising in its construction a tubular-shaped body, a flat flange arranged at one end thereof, radial projections from said flange, the sides of said projections being downturned and located in radial planes with respect to the axis of the tubular body, all substantially as described.

701,477. MEANS FOR COUNTERBALANCING THE MOMENTUM OF RECIPROCATING ELEMENTS. MATTHEW M. FORNEY, New York, N. Y. Filed Dec. 2, 1901. Serial No. 84,992. (No model.)

Claim.—1. The combination with a reciprocating element, of an articulated system of oscillating levers or links, connected to the reciprocating element and forming a guide to insure rectilinear motion thereof, a link coupling said system of levers to a fixed support, and a rod connected to said system of levers and to a crank and moving in opposite direction to the reciprocating element.

2. The combination, with a reciprocating piston and rod, of an articulated system of oscillating levers or links, coupled to the piston-rod and forming a guide to insure rectilinear motion thereof, a link coupling said system of levers to a fixed support, a connecting-rod which is coupled to said system of levers and to a crank, and moves in opposite direction to the piston-rod, and a counterbalance-weight connected to the system of levers and also moving in opposite direction to the piston-rod, the aggregate of said counterbalance-weight and of the weight of the connecting-rod being sufficient to counterbalance the piston and rod.

3. The combination, with a reciprocating piston and rod, of a primary lever connected at one end to the piston-rod, a link coupled to the primary lever and to a fixed support, a connecting-rod coupled at one end to a crank and at the other end to the primary lever, and a counterbalance-weight connected to the end of the primary lever opposite that adjacent to which the piston-rod is connected.

4. The combination, with a reciprocating piston and rod, of a primary lever connected at one end to the piston-rod, a link coupled to the other end of the primary lever and to a fixed support, a secondary lever journaled in fixed bearings and having one of its arms pivotally connected to the primary lever between the link and piston-rod connection thereof, and a connecting-rod coupled to the opposite arm of the secondary lever and to a crank.

5. The combination, with a reciprocating piston and rod, of a primary lever connected at one end to the piston-rod, a counterbalance fixed to the opposite end of the primary lever, a link coupled to the primary lever and to a fixed support, a secondary lever journaled in fixed bearings and having one of its arms pivotally connected to the primary lever between the link and piston-rod connections thereof, and a connecting-rod coupled to the opposite arm of the secondary lever and to a crank.

701,478. BALSTIN MACHINE. FRANK PRATER, Sterling, Ill. Filed Oct. 14, 1901. Serial No. 78,604. (No model.)

Claim.—1. In a balst-machine the combination of mechanism for feeding a series of wire into the machine; mechanism for cutting each wire after they have been introduced a desired distance into the machine; mechanism for supporting each wire while they are being introduced

into the machine, and for releasing the same after they have been so introduced and covered; mechanism for imparting to each covered piece an intermittent lateral movement; mechanism for forming a loop on one end of each of such wires, in succession, during each lateral movement; and mechanism for binding a plurality of such wires into a bundle substantially as set forth.

2. In a balst-machine the combination of mechanism for feeding a continuous wire into the machine; mechanism for cutting a piece from such wire after it has been introduced a desired distance into the machine; mechanism for supporting each wire and releasing the same after it has been so introduced and cut; mechanism for imparting to each covered wire an intermittent, lateral movement; and mechanism for forming a loop on the end of each wire during each lateral movement; substantially as described.

3. In a balst-machine the combination of means for introducing a series of wire strands a desired distance into the machine; means for simultaneously cutting pieces of wire from such strands, and delivering such covered wires to a conveying mechanism; means for conveying such covered wires by an intermittent movement, laterally through and from the machine; and means for forming a loop on one end of each of such wires, in succession, during each lateral progress through the machine; substantially as shown and set forth.

4. In a balst-machine, mechanism for forming a loop on the end of a wire, consisting of the plunger 55, provided with a vertically-movable pin 62; twisting-head 67, provided with a pin 76, adapted to disappear therein; plate 71 provided with the groove 72; jaws 84, and means for operating said mechanism, substantially as shown and set forth.

5. In a balst-machine the combination of mechanism for feeding a series of wire into the machine; mechanism for simultaneously cutting each wire after they have obtained a desired length, consisting of a series of knives 56, having handles 58 pivotally secured on the face-plate 17 in proximity thereof, a slide-bar 29, supporting a series of blocks 36, engaging the handles 58 of the knives, and means for moving the slide-bar 29 so as to cause the knives 56 to cross the ends of the tubes 16 through which the wires pass, whereby each wire is covered; mechanism for supporting each wire, and releasing the covered wire therefrom; mechanism for conveying each covered wire by an intermittent movement, laterally through and from the machine; and mechanism for forming a loop on each wire, in succession, as it passes through the machine; substantially as set forth.

6. In a balst-machine the combination of mechanism for feeding a series of wire strands into the machine; mechanism for guiding and supporting each wire during their progress into the machine, and for releasing the same after a desired length thereof has been obtained; mechanism consisting of a series of guides 19, channeled to receive such wires, and adapted to open so as to permit each wire to drop therefrom; means for supporting each guide, and means for simultaneously opening each guide to permit the release of the wire therefrom; mechanism for simultaneously cutting each wire; mechanism for conveying each covered wire by an intermittent movement laterally through the machine; and mechanism for forming a loop on the end of each wire, in succession, during each lateral progress through the machine; substantially as described.

7. In a balst-machine the combination of mechanism for conveying the wire laterally through the machine, each mechanism consisting of a series of tracks 46, several pair of racks 48 and 47, one pair for each of the tracks 46, and means for imparting to each rack an eccentric intermittent movement; mechanism for forming a loop on one end of each wire as it passes through the machine; and means for delivering a

plurality of wire simultaneously to the conveying mechanism above referred to; substantially as set forth.

8. In a balst-machine the combination of mechanism for introducing a series of wire strands into the machine; mechanism for cutting lengths of wire from such strands after they have been fed a desired distance into the machine; mechanism for delivering each covered length to a loop-forming device; and loop-forming mechanism, consisting of a plunger 55, provided with a vertically-movable pin 62, twisting-head 67, provided with a pin 76 adapted to disappear therein, plate 71 provided with groove 72, jaws 84, and means for operating such loop-forming mechanism; substantially as shown and set forth.

9. In a balst-machine, the combination of mechanism for introducing a series of wire strands a desired distance into the machine; mechanism for simultaneously cutting pieces of wire of a desired length from such strands, and delivering each covered wire to a conveying mechanism; mechanism for conveying such covered wires by an intermittent movement laterally through such machine; mechanism for forming a loop on one end of each of such wires, in succession, during each lateral progress through the machine; and building mechanism, consisting of a series of brackets 100 having recesses 106, a shaft 102, supporting a series of plates 108, adapted to receive and hold the balst-wire; the disk 114 provided with knife 115, the disk 118 carrying the knife 120, the wire 107, coiling-finger 109, secured on the shaft 110, and means for supporting and opening such building mechanism; substantially as shown and described.

10. In a balst-machine wherein the wires are passed laterally through the machine, and formed into balst-ties during each passage, mechanism for forming the completed balst-ties into bundles of a desired size, consisting of the following parts in combination: a series of brackets 100 having recesses 106; a series of plates 108 supported on the shaft 102, and adapted to receive a desired number of completed balst-ties and force the same into a compact bundle in the recesses 106; a coiling-finger 109 secured on the shaft 110, and means for operating such shaft and coiling-finger at desired intervals; a disk 114 provided with the knife 115, and the disk 118 provided with the knife 120, each disk being adapted to draw out a piece of the wire 107 and cut each wire after the same has been coiled about the balst-tie; the rack 183 engaging a pinion 184 on a shaft 103; the hollow shaft 192 and cam 177 fixed thereon, each cam being adapted to impart to the rack 183 an eccentric reciprocating movement; the clutch 188, and means for rotating the same; the hanger 180, and yoke 191 supported thereby; the brace 185 pivotally secured to hanger 180; cam 186 on the cam 177, against which the end of the brace 185 rests, holding the clutch 188 normally out of engagement with the hollow shaft 192; the lever 190, and cam 207, adapted to operate such lever when such parts are vertically in line with one another; the rod 200; lever 201; and the counter-wheel 203, having teeth 204 and a lug 205, and adapted to engage the end of the lever 201, whereby the lever 190 is brought into line with the cam 207, the brace 185, and cam 186 disengaged, and the cam 177 set in motion; substantially as set forth.

701,479. HAIR-FASTENER. ROBERT E. GLASS, Cincinnati, Ohio. Filed June 5, 1901. Serial No. 82,392. (No model.)

Claim.—1. A hair-pin comprising a long leg and a short leg having a connecting-web, an arcuate spring-plate attached at its forward end to the inner face of the short leg at the free end thereof, said spring-plate being adapted to lie with its free end transversely of the long leg and in the direction of the web, and a sleeve slidably mounted upon the short leg of the hair-pin and having an opening in its side through which the spring-plate is adapted to pass when the sleeve is moved in a direction away from the web, said sleeve having an arcuate operating-finger extending beyond the web of the pin and having its end hollowed to fit upon the web of the pin when the sleeve is moved in a direction to expose the spring-plate.

2. A hair-pin comprising a long leg and a short leg having a connecting-web, an arcuate spring-plate attached at its forward end to the inner face of the short leg and at the free end thereof and adapted to normally lie with its free end transversely of the long leg, and a sleeve slidably mounted upon the short leg of the hair-pin and having an opening in its side through which the spring-plate is adapted to pass when the sleeve is moved in a direction away from the web, said sleeve having an operating-finger extending beyond the web of the pin and having its end constructed and arranged to fit upon the web when the sleeve is in position to expose the spring-plate.

3. A hair-pin comprising a long rigid leg and a short rigid leg having a connecting-web, an arcuate spring-plate attached at one end to the

inner face of the short leg and arranged to lie normally with its free end in the direction of the web of the pin, said plate lying in the plane of the two legs of the pin whereby its free end will contact with the long leg of the pin when moved in a direction away from the web, to stop such movement of the plate, and a sleeve slidably mounted upon the short leg of the hair-pin and having an opening arranged to permit of passage of the spring-plate therethrough when the sleeve is moved in a direction away from the web.

701,480. POWER APPLYING AND TRANSMITTING APPARATUS. JAMES E. HARRIS, New York, N. Y. Filed Nov. 24, 1900. Serial No. 37,557. (No model.)

Claim.—1. In a frictional speed-gearing of the class herein described, the rectangular frame composed of the longitudinal ribs *a*, two on each side, united together at their rear ends and having their front ends connected to the plate or head *c*; blocks or frames *g* mounted on said ribs and carrying the friction-rollers *e*, in combination with an including frame *A*, vertical rods *I* and *B*, central bearings for the reception of the power-applying shaft *K*, and power-transmitting shaft *H*, respectively; friction disk or wheel *M* rigidly keyed to shaft *K*, friction disks or wheels *N* longitudinally adjusted and reversible with shaft *H*, and the screw-threaded bolt *d*, having milled head *f*, arranged in the tubular head *d* and engaging with a correspondingly screw-threaded opening in the plate or head *c* of the rectangular frame, substantially as specified.

2. In a frictional speed-gearing of the class herein described, the rectangular frame composed of the ribs *a*, head or plate *c*, and blocks or frames *g* carrying the friction-rollers *e*, in combination with the screw-threaded bolt *d*, located in the tubular head *d*, and engaging with a correspondingly screw-threaded opening in the plate or head *c*; said bolt *d* being adapted for operation through the medium of the friction-wheel *g* located thereon, and the friction-rollers *e* are attached to curved arm *h*, and operating-cords *e*, substantially as specified.

3. In a frictional speed-gearing of the class herein described, the rectangular frame composed of the ribs *a* and plate or head *c*, blocks or frames *g*, the friction-rollers *e*; said frame being capable of longitudinal adjustment in the main frame *A* through the medium of the screw-threaded bolt *d*, arranged in the tubular head *d*, substantially as specified.

4. In a frictional speed-gearing of the class herein described, the curved arm *h*, friction-rollers *e* and cords *e*, in combination with the friction-wheel *g*, and the screw-threaded bolt *d*, whereby the rectangular frame is capable of longitudinal adjustment within its including frame *A*, substantially as specified.

701,481. REGISTER, VENTILATOR, OR THE LIKE. HOWARD S. HART, New Britain, Conn., assignor to Hart & Cooley Company, New Britain, Conn., a Corporation of Connecticut. Filed Mar. 26, 1901. Serial No. 52,936. (No model.)

Claim.—1. A top plate for registers and the like, comprising a plate having an opening, a depending flange adjacent said opening, metal strips stretched across said opening and secured in position by the upset ends thereof.

2. A top plate for registers and the like, comprising a plate having an opening, a depending flange adjacent said opening, metal strips stretched across said opening and secured in position by riveting the ends thereof, one end of said strips crossing another end of said strips.

3. A top plate for registers and the like, comprising a frame and flattened wires attached to said frame and stretched across the same, some of said wires crossing other of said wires, and said wires being arched in cross-section between the points of intersection.

4. A top plate for registers and the like, comprising a flanged frame and flattened wires riveted to the flange of said frame and stretched across the opening, a portion of frame of said wires being arched in cross-section.

5. A top plate for registers, ventilators and the like, comprising a frame, strips secured to said frame forming the bearing and supporting surface of said top plate, the said strips being woven together and arched in cross-section at those portions between the points of their intersection one with the other.

701,482. MOP. HENRY A. HAYDEN, Jersey City, N. J. Filed Aug. 8, 1901. Serial No. 71,201. (No model.)

Claim.—In a mop, the combination with the hollow, oblong metal head having sloping or flared front and ends, the latter provided with internal flanges, and the top plate having open slots 7, the clamping-bar, and the securing-screws engaging said slots in the top plate and screwing into said bar, of the block 10 having grooves in its ends to receive the internal flanges on the ends of the head, and the sponges secured to said block and adapted to project out beyond the head at the front and ends when said block is in place, substantially as set forth.

701,483. FIRE-ESCAPE APPARATUS. ROBERT R. HENNING, Oakland, Cal. Filed July 17, 1900. Serial No. 724,024. (No model.)

Claim.—1. A fire-escape apparatus including a wheeled truck, a reel, a rope ladder composed of side ropes, hand-ropes, spaced ladder-rungs and standards carrying the hand-ropes; in combination with a running-cable permanently affixed to the building, a sheave and a clutch device placed in relation to the sheave, for operation as described.

2. In a fire-escape apparatus a rope ladder composed of side ropes, rungs joining the side ropes together at intervals apart, standards attached to the side ropes by hinged connections that permit movement of the standards in a quarter-circle, and hand-ropes supported by said standards, as described.

3. In a fire-escape apparatus the combination with a wheeled truck, a reel mounted thereon, a rope ladder wound on the reel having side ropes and hand-ropes and connecting rungs and standards; of means for attaching the end of the ladder to a building at a point higher than the truck, means for securing the ladder perpendicularly against the face of the building at a point below the said point of attachment to the building, and tension devices for maintaining tension on the side ropes and the hand-ropes, as described.

4. In a fire-escape apparatus the combination, with a wheeled truck, a reel, a flexible ladder wound on said reel having means for clamping and carrying sections of fire-hose thereon; of a running-cable permanently affixed to the face of a building and extending downward from a sheave at the top and a clutch device located with relation to the sheave as described, as a means of raising the ladder up to and suspending it from the clutch.

5. In a fire-escape apparatus the combination, with a flexible ladder adapted to be wound on a reel; of a ball on the end of the ladder and a clutch device on the building; adapted to seize the ball and comprising a stationary hook and an inclined guard overhanging the point of the hook.

6. The combination on a building-front of a clutch device composed

of a stationary hook projecting outwardly from the building, an inclined gravity-guard overhanging the point of the hook, and a running-cable extending from a sheave above the hook downward along the face of the building.

7. In a fire-escape apparatus, a flexible fire-ladder composed of side ropes, hand-ropes rigid rungs joining the side ropes at intervals, standards supporting the hand-ropes and connected to the rungs by hinged joints and means for clamping sections of fire-hose to the ladder-rungs.

8. A fire-escape apparatus including a wheeled truck, a flexible ladder, a reel for the ladder, tension devices adapted to apply tension to the ropes of the ladder, winding-rollers mounted on the truck, and means attached to a building for raising and lowering the end of the ladder to a point of suspension above the street, comprising a sheave, a running-cable extending over the sheave and down to the ground, and adapted for connection with the winding-roller, and a clutch device located below the sheave and constructed to seize and fasten the end of the ladder to the building, as described.

9. The combination with a truck and a reel mounted thereon, of pliable hose-carrying sections formed of parallel cables united by rigid cross-bars, hose-sections detachably secured to the cross-bars, and coupling devices on the ends of the cable-sections and the hose-sections for joining the same together to increase or reduce the length thereof, said cable-sections forming both a ladder and a carrier for the hose being adapted to wind upon and be unwound from the reel.

701,484. GAME-BOARD. GEORGE E. JOHNSON, Leesville, Pa. Filed Oct. 12, 1901. Serial No. 73,400. (No model.)

Claim.—A game-board having a rail and a series of pockets adjacent thereto, a central depression to receive initially a ball to be dislodged, a circular series of depressions for initially-placed balls surrounding the central depression, a concentric series of posts between the central and outer depressions said posts being interposed in the radial paths of the outer balls to render difficult the dislodgment of the central ball by an outer ball, and a series of posts forming wickets between the outer depressions and rail.

701,485. DISINFECTING DEVICE. LOUIS R. JONES, Conshohocken, Pa., assignor to J. H. Wood Lee Company, Conshohocken, Pa., a Corporation of Pennsylvania. Filed Jan. 18, 1902. Serial No. 90,250. (No model.)

Claim.—1. The combination of a vessel containing a combustible fumigating composition with a bottle set in the center of the said composition and having an upwardly-projecting contracted neck the mouth of which extends above the point reached by the flames from the combustible fumigating composition.

2. The herein-described disinfectant consisting of a vessel containing combustible fumigating composition with a bottle set in the said composition, the mouth of the neck extending above the point reached by the flames of said composition, said bottle having a body of relatively large diameter and an upwardly-projecting contracted neck, the upper part of the body of the bottle and the neck both projecting above the surface of the combustible composition, substantially as set forth.

3. The herein-described disinfectant consisting of a vessel containing combustible fumigating composition with a bottle set in the center of said

composition and having a projecting contracted outlet at the top and wicks coiled in the composition around the bottle, said outlet extending above the point reached by the flames of said composition.

701,486. PENCIL-HOLDER. FRANK J. KAMBER, Colorado Springs, Colo. Filed Mar. 7, 1902. Serial No. 97,079. (No model.)

Claim.—1. As an improved article of manufacture a pencil-holder comprising an outer clamp formed of spring-wire, and having a plurality of upwardly and downwardly extending loops, an inner clamp formed of spring-wire, and having a plurality of upwardly and downwardly extending loops, means connecting the clamps, arranged at the lower corners thereof, and means on one of the clamps for securing the holder in a garment-pocket.

2. As an improved article of manufacture, a pencil-holder comprising an outer clamp formed of a single piece of spring-wire, and having the upwardly-extending loops, the end arms and the cross-bar connecting the end arms, an inner clamp formed of a single piece of spring-wire and having the loops extending above those of the outer clamp, and the end arms terminating in hooks, means connecting the clamps at the lower corners thereof, a layer of soft material secured between the lower portions of the clamps and connected to the cross bar of the outer clamp, and a layer of soft material secured between the lower portions of the clamps, and having a pocket receiving the upper ends of the loops of the inner clamp.

701,487. FEEDING MECHANISM FOR CARDING-MACHINES. HARRY KENT, Boston, Mass. Filed Jan. 2, 1902. Serial No. 92,476. (No model.)

Claim.—1. In a feeding mechanism for carding-machines, the combination with a frame, the rack, the carrier, and the plate pivoted thereon; of a pair of feed-rolls disposed under the plate and provided with gears adapted to engage the rack and at a time, horizontal springs located in

said plate and pressing the feed-rolls normally toward each other, and intermediate gear intermeshing and meshing into the gear with which the feed-rolls are provided, whereby as the feed-rolls are operated by the driver, motion is communicated by one to the other by said intermediate gear, substantially as described.

2. In a feeding mechanism for carding-machines, in combination, the frame; the rack; the carrier; the plate (1) provided with the slots 5 formed with the edges or steps 10; the studs 4, and boxes 6, the latter adapted to slide horizontally in said slots, said boxes being provided with the overlapping edges 9; and the feed-rolls on said studs, substantially as set forth.

3. In a feeding mechanism for carding-machines, in combination, the frame; the rack; the carrier; the plate (1) provided with the slots 5; the studs 4; the hubs 3 of the feed-rolls; the boxes 6 adapted to slide horizontally in said plate and provided with the overlapping edges 9, 9' formed with the extensions 11, 11'; and the downwardly-extending brackets 31 provided with the inwardly-extending steadying-plates 32, substantially as described.

701,488. GAME-COUNTER. WILLIAM J. LAWRENCE, Wilkes-Barre, Pa. Filed Oct. 15, 1901. Serial No. 73,780. (No model.)

Claim.—1. A combined game counter and accumulator consisting of a counter-plate having a plurality of counter-holes adapted to receive a counting-pin, circuit-closing plates arranged adjacent to the counting-plate and adapted to receive the counting-pin at the terminal ends and the electromagnetic bell and circuit connected with the contact-plates, substantially as shown and described.

2. A combined game counter and accumulator comprising in combination a board having counter-plates attached thereto and provided with suitable openings, metallic counter-pins adapted to be inserted in the said openings, the contact-plates arranged beneath the terminal opening, the electromagnetic bell, battery and circuit attached also to the board and connected with the contact-plates, substantially as shown and described.

3. A combined game counter and accumulator comprising in combination a board having counter-plates arranged thereon, said counter-plates having openings produced therein, and marked to designate the points of the game, a metallic counter-pin adapted to be inserted in said openings, contact-plates arranged beneath the terminal opening, the battery, electromagnetic bell, push-button and circuit-wires, all arranged and adapted to operate substantially as described.

4. The combination with a board having counter-plates arranged thereon, said counter-plates having a series of openings produced therein, of the counter-pin adapted to be inserted in the said openings, the lower ends of said pins being metallic, the contact-plates arranged beneath the terminal openings, the circuit-wires, battery and electromagnetic bell, and the switch for opening and closing the circuit, substantially as described.

701,489. PIPE-WRENCH. WILLIAM LOVE, BYR MAINT. PA. Filed Feb. 14, 1901. Serial No. 73,574. (No model.)

Claim.—A pipe-wrench comprising a handle portion, the forward end of said handle portion being curved upward to form the contact point or nose V, an opening formed through the handle portion at the forward

part thereof, a strip of flexible material secured to the under side of the handle portion at a point in the rear of the opening, a bolt passing upward through the flexible strip and through the handle portion and having a nut threaded upon its upper end for the purpose of securing the strip to the handle, said strip passing from its point of attachment upward through the opening around the object to be gripped and back again through the opening, substantially as and for the purpose specified.

701,490. METHOD OF SINKING SHAFTS. GEORGE J. HARR, Saginaw, Mich. Original application filed July 3, 1900. Serial No. 725,614. Divided and this application filed Dec. 3, 1900. Serial No. 72,423. (No model.)

Claim.—The method of building and sinking mine shafts consisting in maintaining a series of shaft-plates in proper relative position to form a transverse section or zone of shafting incapable of lateral separation and capable of independent vertical movement; forcing said plates independently downward; building up the shaft by adding thereto other shaft sections or zones, the plates thereof aligning with those of the sections or zones below, and applying force independently to each of the plates of said added sections to drive said added plates, and the plates below the same downward; and finally removing the material within the shaft.

701,491. INKING-ROLLER FOR PRINTING-PRESS. JAMES F. HARR, Philadelphia, Pa. Assignor, by direct and mesne assignments, of two-thirds to John L. Larson and Charles E. Day, Philadelphia, Pa. Filed Oct. 21, 1901. Serial No. 73,534. (No model.)

Claim.—1. In combination with a printing-press, an inking-roller, eccentric journal-bearings for same, mounted in rotatable trucks and means for limiting the rotating movement of the journal-bearings.

2. In combination with a printing-press, an inking-roller, eccentric journal-bearings rotatably mounted in traveling supports and means for causing a limited rotation of said eccentrics by the initial movement in either direction of the traveling supports.

3. In combination with a printing-press, an inking-roller, eccentric journal-bearings for the shaft of same, trucks for supporting said journal-bearings adapted to roll along the frame of the press, said journal-bearings having a limited relative movement with said trucks, substantially as described.

4. In combination with a printing-press, an inking-roller, eccentric journal-bearings for the shaft of the roller, said journal-bearings being rotatably mounted in trucks but having a limited rotatable movement there-with, said trucks having rotatable engagement with trucks secured to the framework of the press, said eccentric-bearings adapted to shift position

as the roller-chalk changes direction of movement, substantially as described.

5. In combination with a printing-press, an inking-roller having its shaft mounted in spring-compressed journal-bearings, said shaft also rotatable in eccentrics having limited relative movement in trucks adapted to engage with stationary trucks, said eccentrics adapted to shift in position as the roller changes in direction of movement, substantially as described.

701,492. METHOD OF MAKING POOL-BALLS. JULIUS H. MAY, Chicago, Ill. Assignor to the Brunswick-Balke-Clender Company, Chicago, Ill., a Corporation of Ohio. Filed Mar. 24, 1902. Serial No. 59,702. (No specimen.)

Claim.—The herein-described method of manufacturing a composition ball, which consists in first compressing a mass of material into substantially spherical form and simultaneously forming therein cylindrical sockets or cavities in opposite portions thereof, then compressing upon said spherical body or core material of a distinguishing color to produce an annular band and simultaneously forming therein cylindrical apertures, registering with the sockets of the core, next forming or placing within said sockets inserts to afford number-spots and finally compressing a composition upon said core on opposite sides of said band, substantially as described.

701,493. MACHINE FOR PRINTING AND SCORING BOX-BLANKS. FRANCIS MUMFORD, Boston, Mass. Assignor to the Elder Press Company, Dover, N. H., a Corporation of New York. Filed Apr. 16, 1900. Serial No. 12,041. (No model.)

Claim.—1. In a combined machine for printing and scoring box-blanks, the combination of a printing-press, a scoring-press, feeding connections for feeding a single web of material through both of said presses, and driving connections for operating said parts, said driving connections being arranged so that the printing-press may be thrown out of opera-

tion without interfering with the feed of the web or the action of the scoring-press, substantially as described.

2. In a combined machine for producing printed or unprinted box-blanks as desired, the combination of a printing-press, a scoring-press, a web-feeding apparatus for feeding a single web of material through said presses, and driving connections connected to operate both of said presses, and the web-feeding mechanism, to produce printed box-blanks, and to operate the web-feeding mechanism and scoring-press alone when it is desired to produce unprinted box-blanks.

3. In a machine for producing printed or unprinted box-blanks as desired, the combination of a main frame, a platen printing-press arranged at one end of the frame, a platen scoring-press at the opposite end of the frame, web-guide rolls for directing a single web of material through both of said presses, a web-feeding mechanism comprising a pair of intermittently-rotating feed-rolls, arranged to act on a web after the same has passed the printing-press and before it reaches the scoring-press, and an auxiliary feeding-out mechanism at the outgoing end of the machine, consisting of a pair of feed-rolls geared to and actuated from the main feeding mechanism, and a driving-shaft having geared connections for operating the printing and scoring presses and the web-feeding device when it is desired to produce printed box-blanks, and for operating the scoring-press and feeding mechanism without operating the printing-press when it is desired to produce unprinted box-blanks.

701,494. FEED FOR FEEDER. DAVID V. MILLER, Woodsport, N. Y. Filed Oct. 2, 1900. Serial No. 51,513. (No model.)

Claim.—1. A feed comprising a hollow frame having inlet and outlet openings, closures for said openings actuated by the feed, the closure for the inlet-opening being normally out of its operative position for closing the inlet-opening when the feed is unoccupied and being movable automatically independently of the other closure for closing said inlet-opening after the entrance of the feed, and means for holding the closure for the inlet-opening in its normal position, for permitting said closure to move into its operative position to close the inlet-opening, and for moving said closure to its normal position when the other closure is opened by the escaping feed, substantially as and for the purpose described.

2. A feed comprising a hollow frame having an inlet-opening, a plurality of outlet-openings and closures for said inlet and outlet openings, and means connecting the closures for the inlet-opening to the closures for the outlet-openings for varying the position of the closure for the inlet-opening as either of the other closures is opened, substantially as and for the purpose specified.

3. A feed comprising a hollow frame having inlet and outlet openings, closures for said openings actuated by the feed, the closure for the inlet-opening being normally out of its operative position for closing the inlet-opening when the feed is unoccupied and being movable automatically independently of the other closure for closing said inlet-opening after the entrance of the feed, and a reciprocating actuating member connected respectively to the closures for moving the closure for the inlet-opening to its normal position when the other closure is opened by the escaping feed, said actuating member being provided with means for holding the closure for the inlet-opening in its normal position and for permitting said closure to move into its operative position to close the inlet-opening, substantially as and for the purpose specified.

4. A feed comprising a hollow frame having inlet and outlet openings in its ends and an outlet-opening in its top, closures for said inlet and outlet openings, and a reciprocating actuating member having its ends connected, respectively, to the closures for said openings in the ends of the frame, and its intermediate portion connected to the closure for said opening in the top of the frame, substantially as and for the purpose described.

5. A feed comprising a hollow frame having inlet and outlet openings, closures for said openings actuated by the feed, the closure for the inlet-opening being partly open when the feed is unoccupied and being movable automatically for closing said inlet-opening after the entrance of the feed, means connecting the closures for moving the closure for the inlet-opening to its partly-open position when the other closure is opened by the escaping feed, and a catch for holding the closure for the inlet-opening partly open, said catch being forced from its operative position

as the closure for the inlet-opening is additionally opened by the flow when entering the nest, substantially as and for the purpose set forth.

6. A nest comprising a hollow frame having inlet and outlet openings, closures for said openings, an actuating member connected, respectively, to the closures, for varying the position of the closures as the other closure is opened, and a catch for holding the actuating member in its adjusted position, substantially as and for the purpose set forth.

7. A nest comprising a hollow frame having inlet and outlet openings, closures for said openings, a reciprocating actuating member having its ends connected, respectively, to the closures, for opening one of the closures as the other closure is opened, said actuating member being movable independently of one of the closures, and a catch for holding the actuating member in its adjusted position, substantially as and for the purpose described.

8. A nest comprising a hollow frame having inlet and outlet openings, closures for said openings, a reciprocating actuating member having one end connected to the closure for the inlet-opening, and a connection between the closure for the outlet-opening and the other end of the actuating member, said connection being provided with means for permitting the actuating member to move independently of the connection and for causing said member to move simultaneously with said connection, substantially as and for the purpose specified.

9. A nest comprising a hollow frame having inlet and outlet openings, closures for said openings, a reciprocating actuating member having one end connected to the closure for the inlet-opening and movable independently of said closure for a limited distance and also movable simultaneously with said closure, and a connection between the closure for the outlet-opening and the other end of the actuating member, said connection being provided with means for permitting the actuating member to move independently of the connection and for causing said member to move simultaneously with said connection, substantially as and for the purpose set forth.

10. In a nest, the combination of a hollow frame having inlet and outlet openings, a closure for said inlet-opening, an actuating member for the closure, and a catch for holding the actuating member in its adjusted position, said catch being forced from its operative position by the closure, substantially as and for the purpose described.

11. In a nest, the combination of a hollow frame having inlet and outlet openings, a closure for said inlet-opening having a cam or shoulder, an actuating member movable independently of the closure and then movable simultaneously with the closure, and a catch for holding the actuating member in its adjusted position, said catch having a shoulder movable into engagement with the cam or shoulder of the closure for forcing said catch from its operative position, substantially as and for the purpose specified.

12. In a nest, the combination of a hollow frame having inlet and outlet openings, a closure for the inlet-opening having a pin *b* and a cam or shoulder, a reciprocating actuating member having an inclined slot for receiving the pin *b*, a catch for holding the actuating member in its adjusted position, said catch having a shoulder movable into engagement with the cam or shoulder of the closure for forcing said catch from its operative position, and a closure for the outlet-opening connected to the actuating member for actuating the same, substantially as and for the purpose set forth.

13. A nest comprising a hollow frame having inlet and outlet openings, a closure for said outlet-opening, an actuating member, and a link having one end yieldingly connected to said closure and its opposite end connected to the actuating member, said actuating member being movable independently of the link and being movable with said link, substantially as and for the purpose described.

14. In a nest, the combination of a hollow frame having inlet and outlet openings, a closure for the outlet-opening, an actuating member having a pin *b*, a spring-arm having one end fixed to the closure, a link having one end connected to the spring-arm and its other end formed with a lengthwise slot for receiving the pin *b*, and a closure for the inlet-opening connected to the actuating member, substantially as and for the purpose specified.

15. In a nest, the combination of a hollow frame having inlet and outlet openings in its ends, said frame being provided with a stop, closures for said openings hinged at their upper ends, the closure for the inlet-opening being normally partly open, and the closure for the outlet-opening being normally prevented from inward movement by the stop, and a reciprocating actuating member connected to the closures, substantially as and for the purpose set forth.

701,495. BASKET OF TEXTILE MATERIAL. WILLIAM M. MORRIS, Yardville, and BRAD M. DEAPEN, Hingham, N. J., assignors to William M. Morris and Edwin J. Morris, Yardville, N. J., a firm trading as Morris & Company. Filed June 14, 1901. Serial No. 62,010. (No model.)

Claim.—1. A basket or receptacle consisting of a square or oblong strip of textile fabric folded so as to form a receptacle seamless throughout and having single bottom and sides, lapped ends each presenting three thicknesses of material and triangular end flaps folded under the bottom and secured thereto, substantially as specified.

2. The combination of a basket of textile fabric, with a supporting and bracing frame thereof comprising a top rim, and frames with horizontal bottom portions and uprights secured at the upper ends to said rim, and transverse brace-rods connecting the lower portions of said end frames above the bottom portions of the same, substantially as specified.

3. A basket of textile material folded so as to form bottom flaps at the ends of the same, and an external metal supporting-frame for said receptacle having transverse brace-rods around which said bottom flaps are folded and then secured to the bottom of the receptacle, substantially as specified.

4. The combination of a basket of textile fabric, an external metal frame thereof, and a textile strip or band secured externally to the receptacle and confined to upright corner-bars of said frame, substantially as specified.

5. The combination of a basket of textile fabric, an external metal frame thereof, and bands of textile material secured externally to the basket, and forming loops for the reception of the upright corner-bars of the said metal supporting-frame, substantially as specified.

6. The combination of a basket of textile material, an outer metal supporting-frame thereof having end frames with horizontal rails for resting on the floor and transverse strips secured to the bottom of the basket and overlapping said end frames so as to rest thereon and prevent contact of the bottom of the basket with the floor, substantially as specified.

7. The combination of a basket of textile fabric, with an external metal supporting-frame and clips secured to the textile body of the basket, and embracing the upright corner-bars of said metal frame, substantially as specified.

8. A basket or receptacle of textile material having secured thereto adjacent to the bottom an external, tightly-stretched textile band, extending around the receptacle and serving to stiffen and strengthen the same at and near the bottom, substantially as specified.

701,496. SUPPLIER FOR STEAM OR OTHER ENGINES. THOMAS MCKINNEY, Cleveland, Ohio. Filed July 24, 1901. Serial No. 62,612. (No model.)

Claim.—1. A steam-muffler having a series of walls overlapping each other and spaced apart to form an open circuitous passage for the steam, an absorbent, condensing and cushioning material between said walls at each turn of said passage, and means to hold said material in place at said turns, substantially as described.

2. In a steam-muffler, a casing having oppositely-extending and overlapping walls to form an open circuitous steam-passage from its inlet to its outlet, a removable cover substantially over the full length of said passage, an absorbent cushioning material in the turns of said passage and a wire-netting to keep said material in place and maintain a free passage for the steam at the turns, substantially as described.

3. A muffler having a casing with double-walled air-spaces extend-

ing part way across the interior of the muffler from opposite directions, said air-spaces closed to the inside of the muffler and open to the outer air, substantially as described.

4. A muffler having double-walled projections extending into the interior and forming condensing-surfaces and division-walls, and an absorbent condensing and cushioning material between said projections at their base, substantially as described.

701,497. PUMPING POWER FOR OIL-VELLS. GUY D. NEWTON, Cleveland, Ohio. Filed Feb. 6, 1902. Serial No. 62,821. (No model.)

Claim.—1. The combination, in a pumping power for oil-wells, of a vertical shaft, a pull-wheel journaled thereon, an endless internal bevel-rack attached to said pull-wheel by a suitable hinged connection, a horizontal shaft, and a bevel-pinion which drives the said internal bevel-rack whereby a rocking or reciprocating rotary motion is imparted to the pull wheel, substantially as described.

2. The combination in a pumping power for oil-wells, of a suitable beam, a vertical pull-wheel shaft and a horizontal shaft mounted thereon, a pull-wheel journaled on the former shaft and provided with lugs on lower side as shown, a bevel-pinion on the latter shaft, an endless internal bevel-rack driven by said pinion, arms attached to said rack and hinged near their center to the above-mentioned lugs on the pull-wheel, a counterweight in the outer ends of said arms and a small wheel on the end of the horizontal shaft to travel on an oblong ledge centrally located on the rack, substantially as shown and described.

701,498. MACHINE FOR MEASURING THE AREAS OF SURFACES. JONAS E. HIGHTSMITH, Davenport, Iowa. Filed Sept. 7, 1901. Serial No. 74,904. (No model.)

Claim.—In a machine for measuring the areas of surfaces, a measuring-wheel *I*, having a toothed pinion *K*, journaled in a skeleton lever *O*, pivotally connected to a stationary skeleton yoke or bracket *G*, in combination with a toothed segment *M*, suspended on a pivoted lever *K*, having a forward-projecting extension *n*, an adjusting-screw *Q*, arranged on the lever *O*, a rod *P*, loosely interposed between the parts *n* and *Q* and a contractile spring *R* connecting the ends of the levers *N* and *O*, substantially as and for the purpose set forth.

701,499. AUTOMATIC TELEPHONE-EXCHANGE. FRED R. HENNINGSON, Chicago, Ill., assignor of two-thirds to John Anderson, St. Louis, Mo., and H. E. Richardson, St. Louis, Mo. Filed Aug. 27, 1900. Serial No. 22,110. (No model.)

Claim.—1. In a magnet, pole-pieces *N* and *N'* formed of a pair of parallel bars, the polarity of which pieces is maintained by a series of permanent magnets *M* distributed at intervals along said bars substantially as described.

2. A series of permanent magnets, pole-pieces consisting of parallel bars secured to the ends of the permanent magnets, a series of relay-magnets supported on one pole-piece, and a corresponding series of armatures supported on the other pole-piece.

3. A pair of parallel bars, means for maintaining an *N* polarity throughout the length of one bar and an *S* polarity throughout the length of the other bar, a series of relay-magnets supported on one bar, and a corresponding series of armatures supported on the other bar.

4. A pair of parallel bars, means for maintaining opposite polarity throughout the lengths of the bars, a series of pairs of relay-magnets supported on one bar, corresponding armatures supported on the other bar, and means by which an electrical impulse may be sent through a pair of magnets so as to attract one armature and not the other.

5. A pair of parallel bars having opposite polarity, a series of pairs of relay-magnets supported on one bar, corresponding armatures supported on the other bar, a contact-closing device for each armature arranged to be operated thereby, and means by which an electrical impulse may be sent through a pair of magnets so as to attract one armature and not the other.

6. A pair of parallel bars, means for maintaining opposite polarity throughout the lengths of the bars, a series of pairs of relay-magnets supported on one bar, corresponding armatures supported on the other bar, a contact-making device connected to and operated by each armature, a switch-operating magnet connected to each contact-making device, and a telephone line connected to each pair of relay-magnets.

7. A series of pairs of relay-magnets, an armature for each magnet, means for maintaining a similar polarity in all of the armatures, and electrical connections to each pair of magnets, said connections being so arranged that upon sending an electrical impulse through a pair of magnets the poles adjacent to the armatures will be of opposite polarity in respect to each other.

701,500. APPARATUS FOR CONTROLLING THE SPEED OF STEAM-TURBINES. GUNAR O. M. OLSEN, Stockholm, Sweden, assignor to De Laval Steam Turbine Company, a Corporation of New Jersey. Filed June 22, 1901. Serial No. 62,267. (No model.)

Claim.—1. In combination with a steam-turbine and a vacuum-chamber including the same, a valve constructed and arranged to admit air into said chamber and means for actuating said valve.

2. In combination with a steam-turbine and a vacuum-chamber including the same, a valve constructed and arranged to admit air into said chamber and mechanism communicating with said turbine and control-

ing said valve to open the same to admit air into said chamber when said turbine shall have attained a predetermined speed of rotation.

3. In combination with a steam-turbine and a vacuum-chamber including the same, a throttle-valve, an air-valve communicating with said vacuum-chamber and means actuated by said turbine for closing said throttle-valve and subsequently opening said air-valve.

4. In combination with a steam-turbine, a speed-regulator therefor, a throttle-valve controlled by said regulator, a vacuum-chamber including said turbine, and a valve for admitting air into said chamber; the above-said parts being constructed and arranged so that the speed of rotation of said turbine beyond a certain fixed rate shall cause said regulator to shut said throttle and open said air-valve.

5. In combination with a steam-turbine, a speed-regulator therefor and actuated thereby, a throttle-valve controlled by said regulator, a vacuum-chamber including said turbine and a valve for admitting air into said chamber; the above-said parts being constructed and arranged so that said regulator at a certain speed of rotation of said turbine shall operate to close the throttle, and thereafter at a certain higher speed of rotation of said turbine shall operate to open said air-valve.

6. In combination with a steam-turbine having a vacuum-chamber including the same, a speed-regulator for said turbine having the pin 16, a throttle-valve controlled by said regulator, hollow block 18 communicating with said vacuum-chamber and means for opening the air-valve 21 constructed and arranged to be actuated by said regulator-pin 16.

701,501. CATGUT LIGATURE AND SUTURE AND METHOD OF PREPARING SAME. CHARLES E. PARKER, Orange, N. J. Filed Apr. 2, 1900. Serial No. 11,261. (No model.)

Claim.—1. As an article of manufacture, a catgut ligature wound upon an expandable spool, substantially as and for the purpose described.

2. As an article of manufacture, a sterilizing ligature-package consisting of a catgut ligature disposed upon an expandable spool by winding, and relatively securing its ends to maintain tension, substantially as described.

3. As an article of manufacture a sterilizing ligature-package consisting of a catgut ligature disposed upon an expandable spool by winding, and relatively securing its ends to produce extension, and inclosed in a container permeable to sterilizing fluid, substantially as described.

4. The method of treating a catgut ligature consisting in maintaining it under longitudinal tension while subjecting it to the action of a sterilizing fluid, substantially as described.

5. As an article of manufacture, a sterilized ligature-package consisting of a catgut ligature disposed upon an expandable spool by winding, and securing its ends relatively to produce extension, substantially as described.

6. As an article of manufacture a sterilized ligature-package consisting of a catgut ligature disposed upon an expandable spool by winding, and securing its ends relatively to produce extension, and inclosed in a container permeable to sterilizing fluid, substantially as described.

701,502. REAPING-MACHINE. RUTH A. PINK, Pekin, Ill., assignor to Anne Harvester Company, Pekin, Ill., a Corporation of Illinois. Filed Apr. 26, 1901. Serial No. 57,378. (No model.)

Claim.—1. In a harvester, the combination with a main drive-wheel and a frame adapted to rock around the drive-wheel axis, of a push-pole hinged to the rear edge of the frame, a reel pivoted upon the frame, and a jointed connection for adjusting the reel from the driver's platform, said connection having an axis of oscillation located in line with the hinge-axis of the push-pole and the main frame and a pivotal joint located closely adjacent said hinge-axis, substantially as and for the purpose described.

2. In a harvester, the combination with a main drive-wheel and a frame adapted to rock around the drive-wheel axis, of a push-pole hinged to the rear edge of the frame, a reel adjustable vertically and forward and back, connected to said frame, and jointed connections for effecting the adjustments of the reel, said connections each having an axis of oscillation which is located in line with the hinge-axis of the push-pole and the main frame and a pivotal joint closely adjacent said hinge-axis, substantially as and for the purpose described.

3. In a harvester, the combination with a main drive-wheel and a frame adapted to rock around the drive-wheel axis, of a push-pole hinged to the rear edge of the frame, a blade adjustably carried on said frame, and a jointed connection extending to the driver's platform for adjusting the blade, said connection having an axis of oscillation located closely

adjacent the hinge-axis of the push-pole and the main frame and a pivotal joint which in one adjustment of the blade lies in the said hinge-axis, substantially as and for the purpose set forth.

4. In a harvester, the combination with a main drive-wheel, of a main frame mounted to rock around the axis of the drive-wheel, a push-pole hinged to the rear edge of the main frame, a standard rigid with the main frame, an adjusting-rod connected to the standard and extending to the driver's platform, a reel adapted to be adjusted vertically as well as forward and back, rods extending along the push-pole for adjusting the reel, bell-cranks pivoted in line with the hinge-axis of the push-pole, bell-cranks pivoted above said hinge-axis and connections between the upper and lower bell-cranks, and between the upper bell-cranks and the reel, substantially as and for the purpose described.

5. In a harvester of the class described, the combination with a main drive-wheel and a main frame mounted to rock around the axis of the main drive-wheel, of a push-pole hinged to the rear edge of the main frame, a handle-carrier hinged to the main frame, and operating means for tripping the handle-carrier, said means comprising a system of jointed connections, the latter having an axis of oscillation located closely adjacent the hinge-axis of the push-pole and the main frame and a pivotal joint which in one adjustment of the handle-carrier lies in axial alignment with said hinge-axis, substantially as and for the purpose set forth.

6. In a harvester of the type described, in combination, an over-hanging reel, a reel-shaft, a jointed yoke supporting the reel-shaft and whereby the reel may be adjusted vertically and forward and back, and said shaft being extended stubbleward beyond the supporting-bearings, a jointed connection between the extended end of the reel-shaft and the harvester-frame, and a spring attached to one member of the connection and adapted to exert a counterbalancing effect on the reel, substantially as described.

7. In a harvester of the type described, in combination, a reel mounted so as to be adjusted vertically and forward and back, a reel-shaft supported in bearings at the stubble end only, the supported end of said shaft being extended beyond its bearings and a counterbalance applied to said extended end, substantially as described.

701,503. BUTCHER'S BLOCK-SCRAPER. BENJAMIN I. FLOWER, Grants Pass, Ore. Filed Jan. 29, 1902. Serial No. 91,782. (No model.)

Claim.—1. A block-scraper comprising a blade having scraping edges at one end thereof, a handle fixed to the opposite end of the blade, and a handle removably engaged with the blade at a point between the scraping edges and the fixed handle, said blade and curved handle being

constructed to permit of engagement of the handle at opposite sides of the blade.

2. A block-scraper comprising a blade having scraping edges at one end thereof and having a handle fixed at its opposite end, said blade having a perforation therethrough intermediate of the handle and scraping edges, and a supplemental handle having a bolt passed therethrough and engaged with the perforation, said bolt having a clamping thumb-screw engaged removably therewith, whereby the supplemental handle may be engaged at either side of the blade.

701,504. METHOD OF MANUFACTURING STOPPERS FOR BOTTLES, JARS, OR OTHER ARTICLES. JAMES L. RAWSON and EDWARD W. BUNY, Manchester, England. Filed Feb. 27, 1901. Serial No. 46,145. (No specimens.)

Claim.—1. The method of manufacturing a capped cork or stopper with a cap of plastic material consisting in compressing the cork and forming thereon by such compression a recess and retaining-head to receive and retain the plastic material and subsequently compressing around each head and recess in the cork while retained compressed a plastic material which sets hard substantially as described.

2. The method of manufacturing a capped cork or stopper which consists in compressing the cork laterally and longitudinally to form a retaining-head and then compressing thereon while retained compressed a plastic material substantially as described.

3. The method of forming a retaining-head and recess on a cork to receive a cap of plastic material consisting of compressing the cork laterally and longitudinally substantially as described.

701,505. INTERNAL-COMBUSTION ENGINE. FRITZ RECHENBACH, Berlin, Germany. Filed Nov. 23, 1901. Serial No. 53,473. (No model.)

Claim.—1. In an internal-combustion engine, the combination, with means for supplying and exploding a weak mixture of air and fuel in the engine-cylinder, of means for supplying and burning a supplemental fuel charge in said cylinder after the explosion of the weak mixture.

2. In an internal-combustion engine, the combination, with means for introducing a weak mixture of air and fuel into the cylinder, means for confining it therein, and means for thereupon igniting it, of variable mechanism for introducing a supplemental fuel charge into the cylinder after the ignition of the weak mixture.

3. In an internal-combustion engine, the combination, with means for supplying a fixed proportion of a weak mixture of air and fuel to the cylinder and compressing it therein, of means for igniting the said mixture, whereupon an explosion of the same is produced, a speed-controlled mechanism for introducing a variable supplemental fuel charge into the cylinder after the ignition of the weak mixture, whereby a burning of said supplemental fuel charge takes place.

701,505.

701,506. METHOD OF TREATING AIR FOR COOLING AND MOISTENING SAME. WILLIAM F. RICE, Chicago, Ill. Filed Feb. 25, 1901. Serial No. 42,006. (No specimens.)

Claim.—The process which consists in inducing a current of air directly from a source of natural humidity to or through a space to be cooled, placing a gas under compression to materially reduce its volume, removing the heat of compression from said gas, permitting the cooled and compressed gas to expand into said current of air, and delivering into the path of the expanding gas water in such quantity that the expanding gas acts to atomize the water and disseminate the same through the air-current.

rest in the form of a mist or fog; the said air-current being supplied from a natural source in such quantity and humidity that the particles of liquid forced or carried thereby by the expanding gas are at once evaporated and the air-current is thereby cooled and at the same time suitably humidified.

701,507. BRUSH-BROOM. GEORGE W. RICHARDSON, Sparta, Wis., assignor of two-thirds to Edgar W. Dickerson and William W. Hubbell, Sparta, Wis. Filed Mar. 2, 1902. Serial No. 98,427. (No model.)

Claim.—1. In combination with a brush, a handle having pivotal connection therewith, a toothed segment and worm-wheel cooperating with and secured to the respective parts to admit of moving the same to any desired position, substantially as set forth.

2. In combination, a brush, a frame pivoted to the brush, and having an opening and a slot extended from said opening, a toothed segment secured to the brush and arranged in the said slot, and a worm journaled in the opening of the said frame and cooperating with the toothed segment for adjustment of the handle, substantially as set forth.

3. In combination, a brush, a frame pivoted to the brush and having a slot and an opening, a second frame fitted in the opening of the pivoted frame and having oppositely-extended parts overlapping and secured to a side thereof, a toothed segment secured to the brush and passing through the slot of the pivoted frame, and a worm journaled in the frame secured to the pivoted frame and having a thumb-piece, substantially as set forth.

701,508. BOILER-CLEANING COMPOUND. JOHN A. ROBINSON, Berwind, Colo. Filed Apr. 10, 1902. Serial No. 102,948. (No specimen.)

Claim.—The cleaning compound or composition herein described, composed of the water from boiled potatoes, ammonia, sal-soda, coal-oil, black oil, wood-ashes and sulfur, combined with the drag or droppings from animals which chew the cud, in the manner and proportions stated.

701,509. VALVE. JAMES J. BYLAND, Millvale, Pa., assignor to Homestead Valve Manufacturing Company, Homestead, Pa., a Corporation of Pennsylvania. Filed Sept. 22, 1901. Serial No. 78,488. (No model.)

Claim.—1. In a valvular mechanism, the combination of a case or shell divided by transverse partitions into three superposed chambers, an

inlet-passage, a machine supply-passage and an outlet-passage, communicating, respectively, with the several chambers of the case, a supply-valve controlling communication between the inlet and machine supply passages, an exhaust-valve working substantially in line with the inlet-valve and controlling communication between the machine supply and exhaust passages, a shaft entering the casing between the said valves, a cam on said shaft operating the inlet-valve, and a finger or arm on said cam and operatively engaging the outlet-valve.

2. In a valvular mechanism, the combination of a case or shell divided by transverse partitions into three superposed chambers, an inlet-passage, a machine supply-passage and an outlet-passage, communicating, respectively, with the several chambers of the case, a supply-valve controlling communication between the inlet and machine supply passages, a preliminary valve mounted on said supply-valve, an exhaust-valve working substantially in line with the inlet-valve and controlling communication between the machine supply and exhaust passages, a shaft entering the casing between the inlet and outlet valves, a cam on said shaft engaging said preliminary valve to first operate the preliminary valve and then the inlet-valve, and finger or arm on said cam operatively engaging the outlet-valve.

701,510. AIR-SHIP. PETER SARROCKI, Chicago, Ill. Filed Dec. 8, 1901. Serial No. 85,219. (No model.)

Claim.—In an air-ship, the combination with a balloon or gas-reservoir, of a cabin secured thereto and located beneath the reservoir, a main propeller-shaft carrying a propeller and journaled in the rear end of the cabin, an auxiliary propeller-shaft vertically journaled in the cabin, a drum located on the floor of the cabin, an air-compressing cylinder located on the top of the drum and communicating at its bottom therewith, a piston on the auxiliary propeller-shaft and within the air-compressing cylinder, a gas-engine geared to the main and auxiliary propeller-shafts, an air-tank communicating with the air-compressing cylinder, an oil-tank communicating with said air-tank and with the cylinder of the gas-engine, and means to throw the propeller-shafts in and out of gear with the crank-shaft of the engine, substantially as described.

701,511. CALENDERING-MACHINE. LOUIS SCHREIER, Barrow-Kittershausen, Germany. Filed Oct. 1, 1901. Serial No. 77,808. (No model.)

Claim.—1. In a calendering-machine, the combination of the two calendering-rollers and means for separating one roller from the other, said means comprising a cam, a friction drive connection between said cam and one of the rollers and means for holding said cam against rotation with the roller, substantially as described.

2. In combination, the two rollers, a ring having frictional connection with one roller to be driven thereby, a cam on the ring and means for normally holding the cam and ring against rotation with the roller, said cam being arranged to separate the rollers, substantially as described.

3. In combination, the two rollers, a ring driven by friction from one roller, a cam carried by the ring to separate the rollers and a detent for holding the ring and cam normally against rotation, substantially as described.

4. In combination, the rollers, a friction-ring at each end thereof, a cam on each ring for separating the rollers and detent means for normally holding the rings against rotation, substantially as described.

5. In a calendering-machine, in combination with one of the calendering-rollers, two lifting-cams, two rings carrying the cams and frictionally mounted on each end of the roller, and two detents, arranged and operating substantially as and for the purpose set forth.

6. In a calendering-machine, in combination with one of the calendering-rollers, a cam-ring frictionally held at each end thereof and a spring-detent and hand-lever, arranged and operating substantially as and for the purpose set forth.

7. An appliance for separating the rollers of a calendering-machine during the passage of a seam between them without relieving the pressure of the lifted roller upon the other rollers, the said appliance comprising a ring C carrying a pair of cam-surfaces D and being frictionally mounted on each end of one of the rollers A, and a spring-detent E, rocking-shaft F and hand-lever G, arranged and operating substantially as and for the purpose set forth.

701,512. ROTARY CULTIVATOR. JOHN SCOTT, Edinburgh, Scotland. Filed Jan. 7, 1902. Serial No. 82,798. (No model.)

Claim.—A cultivator-blade consisting of a bar bent to form an open helix having end-shafts at its ends and having driving-elements at its ends, the convolutions of the helix having their edges sharpened and said convolutions being unsupported excepting at the ends of the helix curve by the adjacent convolutions.

701,518. METALLIC RAILWAY-TIE. CHARLES S. SHALLENBERGER, Milwaukee, Wis., assignor, by mesne assignments, of one-half to M. J. Hurley, St. Louis, Mo. Filed Aug. 19, 1901. Serial No. 78,537. (No model.)

Claim.—1. A tie, consisting of a metallic plate having its sides bent downwardly and being cut to form the tongues 2 near its top, the said

tongues 2 being bent outwardly and being adapted to receive the rail-ends, and means for holding the rails upon the rail-ends, substantially as specified.

2. A metallic tie, consisting of a section of sheet metal bent to form a top 4, the sides 5 and the base 6 and being cut out at the top to form the tongues 2, said tongues 2 being bent outwardly and being adapted to receive the rail-ends, and means whereby the rails may be locked upon the tie, substantially as specified.

3. A metallic tie consisting of a section of sheet metal bent to form a top 4, the inclined sides 5 and the base 6, and cut out at the top to form the tongues 2, said tongues being bent outwardly to receive the rail-ends, said top having also bolt-holes 3 and openings 10 formed therein adjacent to the rail-ends, tongues extending downwardly from said openings 10 for holding the bolt-heads rigidly against turning, and means whereby the rails may be locked upon the tie, substantially as specified.

701,514. COMBINED SPRING AND FRICTION DRAFT-RIGGING. CHARLES S. SHALLENBERGER, Milwaukee, Wis., assignor, by mesne assignments, of one-half to M. J. Hurley, St. Louis, Mo. Filed Sept. 23, 1901. Serial No. 78,554. (No model.)

Claim.—1. The combination with a draw-bar, of a friction-casing having an integral wedge-shaped friction-plate at its rear end and arranged to slide with the draw-bar, a draw-bar connection, and the following friction mechanism all contained within said casing: a front friction-plate adapted to receive both the outward and inward pressure of the draw-bar, opposite side friction-plates, and suitable yielding connections for holding the said parts in proper position, substantially as specified.

2. A combined spring and friction draft-rigging, consisting of a movable friction-casing having an integral wedge-shaped friction-plate at its rear end and arranged to slide with the draw-bar, a front friction-plate mounted adjacent to the friction-casing and arranged to receive both the draft and buffing shocks, two opposite movable side friction-plates mounted between the front friction-plate and the rear friction-plate, and means for holding the said parts in proper adjustment to receive the inward and outward pressure of the draw-bar, substantially as specified.

3. In a combined spring and friction draft-rigging, the combination of a draw-bar, a movable casing having an integral wedge-shaped friction-plate at its rear end, and arranged to slide with the said draw-bar, and the following friction mechanism all contained within said casing: a buffing or draft plate, a front friction-plate arranged to receive both the buffing and draft shocks, a buffing or draft spring interposed between the buffing-plate and the front friction-plate, two side plates interposed opposite each other between the front friction-plate and the rear friction-plate, and means for maintaining said plates in position, substantially as specified.

4. The improved draft and buffer rigging, comprising the casing having a wedge-shaped friction-plate at one end, a wedge-shaped front friction-plate loosely arranged to slide in the opposite end of said casing, with its wedge facing the wedge of the plate first mentioned, opposite side friction-plates 12, the ends of which are beveled to engage the beveled faces of said end friction-plates, said side friction-plates having recesses 15, a bolt 16 extending through said recesses, spring 14 mounted one in each recess, and a draw-bar connection whereby the said front friction-plate is adapted to receive both the draft and buffing shocks, substantially as herein specified.

701,515. CAR-BOLSTER. CHARLES S. SHALLENBERGER, Milwaukee, Wis., assignor, by mesne assignments, of one-half to M. J. Hurley, St. Louis, Mo. Filed Nov. 14, 1901. Serial No. 82,318. (No model.)

Claim.—A car-bolster, comprising an upper member 1, the middle of which is broader than its side portions and a lower member, a center bearing 3 connecting said members, reinforcing-ribs integral with said center bearing and extending between said members, and the said members converging and being combined near their outer ends, a spring-seat formed at each end of the bolster, walls around the said spring-seat, side walls 10 extending upwardly from the spring-seat and forming bearings to receive the standards whereby the bolster is held in position, and the side bearings 12 formed integral with the upper side of the bolster for receiving the side bearings of the body-bolster, substantially as specified.

701,515.

701,516. WATER-GAGE FOR BOILERS. EDWARD F. SHALLOW, West Philadelphia, Pa. Filed Feb. 17, 1902. Serial No. 94,362. (No model.)

Claim.—1. In a water-gage, a boiler, a glass tube, hangers, superposed chambers arranged in said hangers, an inlet connecting the chambers with each other, a valve arranged in said lower chamber controlling the boiler-outlet and permitting of the entrance of water or steam from said boiler into said chambers, an angular passage connecting the upper chamber with said tube, a valve centrally arranged in said upper chamber and having a differential face in alignment with the flow of water or steam from said boiler into said tube, and a drip-cock leading from the lower chamber of one of said hangers directly to the atmosphere.

2. In a water-gage, a boiler, a glass tube, hangers, superposed chambers

hangers arranged in said hangers, an inlet connecting the chambers with each other, a valve arranged in said lower chamber controlling the boiler-outlet and permitting of the entrance of water or steam from said boiler into said chambers, an angular passage connecting the upper chamber with said tube, a valve centrally arranged in said upper chamber and having a differential face in alignment with the flow of water or steam from said boiler into said tube, and a drip-cock leading from the lower chamber of one of said hangers directly to the atmosphere.

701,517. LOCK FOR OVERHEAD-TROLLEY TRACKS. SAMUEL J. SHARP, Wheeling, W. Va., assignor of three-fourths to Herbert E. Dunlap, Louis F. Stille, and Henry E. Stille, Wheeling, W. Va. Filed May 8, 1901. Serial No. 58,244. (No model.)

Claim.—1. In an automatic switch-lock of the character described, the combination with an overhead track, hangers therefor and a turn-table, of a bar pivoted to the hanger next the switch, a notch provided in said track in which the point of said bar normally lies, a weight suspended from said bar at a point between its pivotal connection with the hanger and the track, and a long bar 11 secured on said turn-table, said bar 11 being adapted to tip up and hold the front end of the pivoted bar to leave the track clear when the switch is closed, substantially as described.

2. In an automatic switch-lock for overhead-trolley tracks, the combination with the track, hanger and turn-table, of a bar pivoted on the track-hanger next the switch, said track provided with a notch therein, the point of said bar adapted to normally lie in said notch to lock the switch, a weight suspended from said bar and adapted to normally hold the said bar in place in said notch, and a rod fixed to said switch-block and adapted to tip the front end of said bar from the notch to clear the track when the switch is closed by the turn-table, all substantially as shown and described.

3. In an automatic switch-lock for overhead-trolley tracks, the combination with the track 3, hanger 1 and turn-table 5, of the bar 6, pivot 9, the track 3 provided with the notch 7, the weight 8, and the rod 11, all substantially as and for the purposes set forth and described.

701,518. FEED-WATER HEATER. FRANK W. SUTHER, Spokane, Wash. Filed Dec. 12, 1901. Serial No. 85,908. (No model.)

Claim.—1. The combination in a feed-water heater, of a boiler, a fire-box, a flattened pipe adapted to be placed in the fire-box of the boiler, a double check-valve, a chamber containing the same, a water-supply pipe in communication with said chamber, a circulating-pipe extending between the water-space of the boiler and said chamber, said circulating-pipe being of a diameter less than the water-supply pipe, a pipe extending between said chamber and the heater-pipe, and a discharge-pipe extending from the heater-pipe to a point within the boiler.

2. The combination in a feed-water heater, of a boiler, a fire-box, a single heater-pipe extending in a substantially horizontal plane within the fire-box and bent into a serpentine or wavy line, means for supporting said pipe at a point immediately above the grate, and supply and discharge pipes communicating respectively with the opposite ends of said pipe.

3. The combination in a feed-water heater, of a boiler, a fire-box, a heater-pipe arranged within the fire-box, thinblades extending between the wall of the fire-box and the shell of the boiler, blow-off pipes connected to said heater-pipe and extending through the said thinblades, said blow-off pipes acting to support the said heater-pipe, and water supply and discharge pipes communicating with said heater-pipe.

4. The combination in a feed-water heater, of a boiler, a fire-box, a heater-pipe bent into a serpentine or wavy line and located within the fire-box, a series of supporting and blow-off pipes connected to the lower bands of the pipe and extending out through the shell of the boiler, and water supply and discharge pipes communicating with said heater-pipe.

5. The combination in a feed-water heater, of a boiler, a fire-box, a heater-pipe bent into a serpentine or wavy line and located within the fire-box, supporting and blow-off pipes connected to the lower bands of

the heater-pipe, thinblades extending between the wall of the fire-box and the shell of the boiler and forming passages for said supporting and blow-off pipes, a double check-valve, a valve-chamber, containing the same, a water-supply pipe communicating with the valve-chamber and having a valve-seat at the lower end of the chamber, a circulating-pipe connecting the boiler and the check-valve chamber and of a diameter less than that of the water-supply pipe, a pipe extending between the valve-chamber and one end of the heater-pipe, and an oppositely-disposed discharge-pipe extending between the opposite end of the heater-pipe and the interior of the boiler.

6. In a feed-water heater, a boiler, a fire-box, a heater-pipe located within the fire-box, a water-supply pipe therefore, a water-discharge pipe extending from the opposite end of the heater-pipe through the front flue-sheet of the boiler and perforated to permit of the discharge of water, a threaded sleeve to which the end of the pipe is secured, and a threaded closing-pipe carried by said sleeve to close the end of the pipe, substantially as specified.

701,519. VEHICLE-SPOKE PULLER. CHARLES W. RICHMOND, Independence, Mo. Filed Sept. 20, 1901. Serial No. 74,968. (No model.)

Claim.—The combination of a lever having one end provided with a handle-section, its opposite end having a head formed thereon from which protrude short shaft-sections, toothed cylinders journaled on the shafts, a retaining-plate held upon one of the shafts and adapted for engagement with the opposite shaft, and a fulcrum-bracket secured to the lever adjacent the head, the said brackets consisting of a body portion having arms protruding therefrom and each provided with a series of apertures through one of which is designed to pass a bolt for securing the said bracket to the lever, the opposite end of the bracket having a semi-circular recess formed therein, substantially as shown and described.

701,520. TELESCOPE. FREDERICK L. SMITH and HARRY D. GORE, Buffalo, N. Y., assignors to Colson Tool and Optical Company, Buffalo, N. Y. Filed Aug. 4, 1901. Serial No. 78,284. (No model.)

Claim.—1. The combination with an including tube, of a lens-tube therein made up of independent sections, means at one end of the including tube against which one tube-section chaps, and a device at the other end of said including tube adapted to jam the sections of said lens-tube tightly together, substantially as set forth.

2. The combination with an including tube, of a lens-cell therein, one or more spacing-shells therein, said lens-cell and spacing shell or shells constituting a sectional inner tube, and end caps having screw-threaded engagements with the opposite ends of said including tube and adapted to jam said lens-cell and shell or shells together between the end caps, substantially as set forth.

3. The combination with an including tube, having screw-threaded ends, of a lens-cell at or near each end of said tube, a spacing-shell between said cells, said cells and shell constituting a sectional inner tube, and end caps having screw-threaded flanges engaging the screw-threaded ends of said including tube and having shoulders engaging the ends of said inner sectional tube and adapted to jam the sections thereof tightly together, substantially as set forth.

701,521. APPLIANCE FOR TREATING HORSES' LEGS WITH WATER. JOHN T. DUNN, New York, England, assignor to ALFRED DUNN, Ltd., London, England. Filed Jan. 22, 1901. Serial No. 64,572. (No model.)

Claim.—An apparatus for treating horses consisting of flexible perforated tubes, one for each leg, each of said tubes being connected with

a nozzle H having three branches, a distributing-nozzle arranged to be placed on the horse's back and having four outlets, the reducing-liners in the said outlets, a tube extending from each of the four outlets to the flexible perforated tubes at the horse's legs, and a tube leading to the said distributing-nozzle whereby all the legs of the horse may be supplied at once.

701,522. AUTOMATIC SWITCH FOR PNEUMATIC CARRIERS.
FRED R. YAMET, Indianapolis, Ind., assignor to the Talcott Pneumatic Service Company, Indianapolis, Ind., a Corporation of Indiana. Filed Oct. 17, 1901. Serial No. 78,964. (No model.)

Claim.—1. In a switch-actuating mechanism for pneumatic carriers, the combination with a shaft, a trigger loosely mounted thereon, a ratchet secured on said shaft, and a pawl pivoted to the trigger for engaging the ratchet when the pawl is actuated, of a catch for engaging the pawl and holding it in its actuated position.

2. In a switch-actuating mechanism for pneumatic carriers, the combination with a shaft, a trigger loosely mounted thereon, a ratchet secured on said shaft, a pawl pivoted to the trigger for engaging the ratchet when the pawl is actuated, and a spring for normally holding the pawl out of engagement with the ratchet, of a catch for engaging and holding the pawl after it has been actuated so that it will keep in engagement with the ratchet.

3. In a switch-actuating mechanism for pneumatic carriers, the combination with a shaft, a trigger loosely mounted thereon, a ratchet secured on said shaft, a pawl pivoted to the trigger for engaging the ratchet when the pawl is actuated and a spring for normally holding the pawl out of engagement with the ratchet, means for returning the trigger mechanism after it has been actuated, and a stationary means for engaging the catch in its return movement to disengage it from the pawl.

701,523. PROCESS OF MAKING ALKYL ETHERS OF CIRCONE-ALKALOID CARBONIC ACIDS. HERBERT TERN, Frankfurt-on-the-Main, Germany, assignor to Veredigte Glanzfabriken, Rummer & Co., Gesellschaft mit beschränkter Haftung, Frankfurt-on-the-Main, Germany, a Firm. Original application filed Apr. 24, 1901, Serial No. 67,222. Divided and this application filed Jan. 8, 1902. Serial No. 14,904. (No specimens.)

Claim.—1. A process for the manufacture of the alkyl ethers of the circone-alkaloid carbonic acids which consists in causing the alkyl ethers of alkyl carbonic acids to act on the circone-alkaloids substantially as described.

2. A process for the manufacture of the ethyl ethers of the circone-alkaloid carbonic acids which consists in causing the alkyl ethers of ethyl carbonic acid to act on the circone-alkaloids substantially as described.

3. A process for the manufacture of the ethyl ether of quinic carbonic acid which consists in causing the alkyl ethers of ethyl carbonic acid to act on quinic substantially as described.

701,524. STEAM-TRAP. FREDERICK TOWN, Brooklyn, Mass. Filed July 3, 1901. Serial No. 66,901. (No model.)

Claim.—1. In a steam-trap or analogous apparatus, the combination of a discharge-passage, a steam-chamber communicating therewith, a valve, controlling the discharge-passage and the entrance to the steam-chamber, a heat-expandable valve-controller in heat-conductive proximity to the steam-chamber, the discharge-passage and steam-chamber being so disposed with relation to each other that liquids flow through the discharge-passage without entering the steam-chamber, substantially as described.

2. In a steam-trap or analogous apparatus, the combination of a discharge-passage, a steam-chamber communicating therewith, a valve, controlling the discharge-passage and the entrance to the steam-chamber, a heat-expandable valve-controller in heat-conductive proximity to the steam-chamber, an elastic cushion, whereon the valve-controller is abutted, the

discharge-passage and steam-chamber being so disposed with relation to each other that liquids flow through the discharge-passage without entering the steam-chamber, substantially as described.

3. In a steam-trap or analogous apparatus, the combination of a discharge-passage, a steam-chamber communicating therewith, a valve, controlling the discharge-passage and the entrance to the steam-chamber, a heat-expandable valve-controller in heat-conductive proximity to the steam-chamber, the discharge-passage and steam-chamber being so disposed with relation to each other that liquids flow through the discharge-passage without entering the steam-chamber, and means whereby the valve-controller may be manually operated to lift the valve from its seat substantially as described.

4. In a steam-trap or analogous apparatus, the combination of a discharge-passage, a steam-chamber communicating therewith, a valve, controlling the discharge-passage and the entrance to the steam-chamber, a heat-expandable valve-controller in heat-conductive proximity to the steam-chamber and means whereby the valve-controller may be manually operated to lift the valve from its seat against the stress of the elastic cushion, the discharge-passage and steam-chamber being so disposed with relation to each other that liquids flow through the discharge-passage without entering the steam-chamber, substantially as described.

5. In a steam-trap or analogous apparatus, the combination of a discharge-passage, a steam-tube of heat-expandable material, a valve connected therewith controlling the discharge-passage and the entrance to the steam-tube, the steam-tube adapted to receive steam issuing from the discharge-passage, connections between the expandable steam-tube and the valve whereby expansion of the tube is accompanied by closure of the valve, the discharge-passage being so located that liquids passing therethrough flow away from effective heat-conductive proximity to the steam-tube.

6. In a steam-trap or analogous apparatus, the combination of a discharge-passage, a steam-tube of heat-expandable material, a valve connected therewith controlling the discharge-passage and the entrance to the steam-tube, the steam-tube provided with device whereby circulation of steam issuing from the inlet-pipe is induced through the steam-tube, connections between the expandable steam-tube and the valve whereby expansion of the tube is accompanied by closure of the valve, the discharge-passage being so located that liquids passing therethrough flow away from effective heat-conductive proximity to the steam-tube.

7. In a steam-trap or analogous apparatus, the combination of a discharge-passage, a steam-chamber communicating therewith, a valve, controlling the discharge-passage and the entrance to the steam-chamber, a heat-expandable valve-controller in heat-conductive proximity to the steam-chamber, the discharge-passage and steam-chamber being so disposed with relation to each other that liquids flow through the discharge-passage without entering the steam-chamber, and connections with the valve whereby the valve may be opened at will independently of the normal operation of the valve-controller, substantially as described.

8. In a steam-trap or analogous apparatus, the combination of a discharge-passage, a steam-chamber communicating therewith, a valve, controlling the discharge-passage and the entrance to the steam-chamber, a heat-expandable valve-controller in heat-conductive proximity to the steam-chamber, an elastic cushion, whereon the valve-controller is abutted, the discharge-passage and steam-chamber being so disposed with relation to

each other that liquids flow through the discharge-passage without entering the steam-chamber, and connections with the valve whereby the valve may be opened at will independently of the normal operation of the valve-controller, substantially as described.

9. In a steam-trap or analogous apparatus, the combination of a discharge-passage, a steam-chamber communicating therewith, a valve, controlling the discharge-passage and the entrance to the steam-chamber, a heat-expandable valve-controller in heat-conductive proximity to the steam-chamber, the discharge-passage and steam-chamber being so disposed with relation to each other that liquids flow through the discharge-passage without entering the steam-chamber, and means whereby the valve-controller may be manually operated to lift the valve from its seat and connections with the valve whereby the valve may be opened at will independently of the normal operation of the valve-controller, substantially as described.

10. In a steam-trap or analogous apparatus, the combination of a discharge-passage, a steam-chamber communicating therewith, a valve, controlling the discharge-passage and the entrance to the steam-chamber, a heat-expandable valve-controller in heat-conductive proximity to the steam-chamber and means whereby the valve-controller may be manually operated to lift the valve from its seat against the stress of the elastic cushion, the discharge-passage and steam-chamber being so disposed with relation to each other that liquids flow through the discharge-passage without entering the steam-chamber, and connections with the valve whereby the valve may be opened at will independently of the normal operation of the valve-controller, substantially as described.

11. In a steam-trap or analogous apparatus, the combination of a discharge-passage, a steam-tube of heat-expandable material connected therewith, controlling the discharge-passage and the entrance to the steam-tube, the steam-tube adapted to receive steam issuing from the discharge-passage, connections between the expandable steam-tube and the valve whereby expansion of the tube is accompanied by closure of the valve, the discharge-passage being so located that liquids passing therethrough flow away from effective heat-conductive proximity to the steam-tube, and connections with the valve whereby the valve may be opened at will independently of the normal operation of the valve-controller.

12. In a steam-trap or analogous apparatus, the combination of a fluid-discharge pipe, a valve in the same, the said valve controlled by a heat-expandable valve-controller, and so located that liquids passing through the discharge-pipe past the valve flow away from the valve-controller, a steam-opening leading to the controller from the outlet side of the valve, so that steam, to approach the controller must first pass the valve, substantially as described.

13. In a steam-trap or analogous apparatus, the combination of a fluid-discharge pipe, a valve in the same, a tubular valve-controller secured to the valve, an aperture from the outlet side of the valve leading to the interior of the tubular controller, a casing surrounding the controller, an aperture in the controller communicating with the interior of the said casing, and drain-apertures from the casing to the discharge-pipe, substantially as described.

14. In a steam-trap or analogous apparatus, the combination of a discharge-passage, a steam-chamber branching from and communicating therewith, a valve, controlling the discharge-passage and the entrance to the steam-chamber, a heat-expandable valve-controller in heat-conductive proximity to the steam-chamber, the discharge-passage and steam-chamber being so disposed with relation to each other that liquids flow through the discharge-passage without entering the steam-chamber, substantially as described.

15. In a steam-trap or analogous apparatus, the combination of a discharge-passage, a steam-chamber branching from and communicating therewith, a valve, controlling the discharge-passage and the entrance to the steam-chamber, a heat-expandable valve-controller in heat-conductive proximity to the steam-chamber, an elastic cushion, whereon the valve-controller is abutted, the discharge-passage and steam-chamber being so disposed with relation to each other that liquids flow through the discharge-passage without entering the steam-chamber, substantially as described.

16. In a steam-trap or analogous apparatus, the combination of a discharge-passage, a steam-chamber branching from and communicating therewith, a valve, controlling the discharge-passage and the entrance to the steam-chamber, a heat-expandable valve-controller in heat-conductive proximity to the steam-chamber, the discharge-passage and steam-chamber being so disposed with relation to each other that liquid flows through the discharge-passage without entering the steam-chamber, and means whereby the valve-controller may be manually operated to lift the valve from its seat substantially as described.

17. In a steam-trap or analogous apparatus, the combination of a discharge-passage, a steam-tube of heat-expandable material branching therefrom, a valve connected therewith controlling the discharge-passage and the entrance to the steam-tube, the steam-tube adapted to receive steam issuing from the discharge-passage, connections between the expandable steam-tube and the valve whereby expansion of the tube is accompanied by closure of the valve, the discharge-passage being so located that liquids passing therethrough flow away from effective heat-conductive proximity to the steam-tube.

companied by closure of the valve, the discharge-passage being so located that liquids passing therethrough flow away from effective heat-conductive proximity to the steam-tube.

18. In a steam-trap or analogous apparatus, the combination of a discharge-passage, a steam-tube of heat-expandable material branching therefrom, a valve connected therewith controlling the discharge-passage and the entrance to the steam-tube, the steam-tube provided with device whereby circulation of steam issuing from the inlet-pipe is induced through the steam-tube, connections between the expandable steam-tube and the valve whereby expansion of the tube is accompanied by closure of the valve, the discharge-passage being so located that liquids passing therethrough flow away from effective heat-conductive proximity to the steam-tube.

19. In a steam-trap or analogous apparatus, the combination of a discharge-passage, a steam-chamber branching therefrom and communicating therewith, a valve, controlling the discharge-passage and the entrance to the steam-chamber, a heat-expandable valve-controller in heat-conductive proximity to the steam-chamber, the discharge-passage and steam-chamber being so disposed with relation to each other that liquids flow through the discharge-passage without entering the steam-chamber, and connections with the valve whereby the valve may be opened at will independently of the normal operation of the valve-controller, substantially as described.

701,525. SAFETY-VALVE. WILLIAM S. WAREHAM, Wellesley, Mass. Filed Jan. 12, 1901. Serial No. 62,903. (No model.)

Claim.—1. A safety-valve for a boiler, comprising a member having a plurality of openings or passages from the fire-box to the external atmosphere, and a cover for part of said openings, said cover being provided with an opening to normally admit air directly to the fire-box and being also free to be moved outward by excessive pressure within the fire-box.

2. A safety-valve for a boiler, comprising a member having a plurality of openings or passages from the fire-box to the external atmosphere, a cover for part of said openings, a support for said cover having a passage to normally admit air directly to the fire-box, said cover being permanently free to be moved outward by excessive pressure within the fire-box.

3. A safety-valve for a boiler, comprising a fire-box door having a perforated portion, a permanently-open tube free to slide relatively to said perforated portion, and a cover attached to said tube and movable therewith and having a diameter to cover the perforations around the tube, said cover being permanently free to be moved outward to relieve excessive internal pressure in the fire-box.

4. A heater provided with a vent or outlet communicating with the fire-box, a substantially horizontal guide adjacent to said outlet, and a valve adapted to close said outlet and having a slide movable on said guide from the closed position to the open position of the valve, the guide supporting the valve in either of said positions.

701,526. STEREOSCOPE. HAWLEY C. WHITE and HARRIS C. WHITE, North Bennington, Vt., assignors to E. C. White Co., North Bennington, Vt., a Corporation of Vermont. Filed Apr. 18, 1901. Serial No. 58,081. (No model.)

Claim.—1. As a constituent member of a stereoscope, a shaft consisting of an upper and an under metallic plate with a space between them, the margin of one of said plates being fashioned with an upturned semi-tubular flange and the margin of the other with a substantially tubular flange which closely envelopes the semi-tubular flange of the former plate, the inclined flange thus practically forming a strut within the tubular structure so constituted which stands transversely to the plane of the shaft, substantially as specified.

2. As a constituent member of a stereoscope, a shaft consisting of two metallic plates with a space between them, having their margins interlocked by a joint whereof the edge of one member has a flange upturned transversely to the plane of the shaft, and having a longitudinal depression in one plate sunk to a depth to contact with the inner surface of the other plate, substantially as specified.

3. As a constituent member of a stereoscope, a shaft consisting of two metallic plates having their margins interlocked by a joint whereof the edge of one member has a flange upturned transversely to the plane of the shaft, both plates having shallow depressions oppositely disposed so as when assembled to contact with each other, substantially as specified.

4. As a constituent member of a stereoscope, a shaft consisting of two metallic plates having margins interlocked by a joint whereof the edge of one member has a flange upturned transversely to the plane of the shaft, with a space between said plates, one of said plates projecting forwardly of the lens-frame and having provisions for connecting with the hood, and the other having provisions to receive and connect with the lens-frame, substantially as specified.

5. As an improved member of a stereoscope, a lens-frame consisting of a metallic face and a metallic back plate, the face-plate being provided with shallow flanged sockets to receive and maintain correct lateral position of the lenses; the back plate having forwardly-projecting inclined flanged rims to contact with the back sides of the lenses and in opposition with the aforesaid sockets; means for holding said plates in correct co-junctive position, and means for drawing them together so as to bind the interposed lenses immovably in their positions in the frame.

6. As an improved member of a stereoscope, a lens-frame consisting of a metallic face-plate, the main central field of which is struck up above the plane of its margin approximately the thickness of the lenses, provided with shallow flanged sockets to receive and maintain correct lateral position of the lenses; in combination with a back plate having forwardly-projecting inclined flanged rims to contact with the back sides of the lenses and in opposition with the aforesaid sockets; and having also a marginal flanged groove to receive the edges of said plates, and means in connection therewith for holding said hood and plates in conjunction and means for binding said plates to each other.

7. In combination with a shaft consisting of two metallic plates marginally locked together with a space between them; of a lens-holder consisting of a metallic back plate having a peripheral-flanged groove, and a metallic face-plate with provisions between said back and face plates for receiving and holding the lenses in correct position; means for lock-

ing and confining said shaft and lens-frame together; and a hood flanged to connect with the groove of the back plate and locked to the shaft, substantially as specified.

8. The combination in a stereoscope, with the shaft and lens-frame of a septum consisting of a core of material suitable for holding a nail or screw-thread, and a metallic sheath including the same provided with a perforated flange or flanges which overlap the core, and fastening devices adapted to cooperate with said perforated flange for attaching the septum to the shaft, substantially as specified.

9. As a constituent member of a stereoscope, a picture-holder consisting of a plate of metal having a tubular head extending along its side edges, said tubular feature containing and holding by their tangs wire guards for supporting the pictures, substantially as specified.

10. The described picture-holder-consisting of a metallic plate having tubular headed edges and cord-supporting wire guards, the ends of each of which are of differential length so that the long end of one guard shall break joint over the opposing contiguous ends of the guards, substantially as specified.

11. The combination in a stereoscope, of a shaft provided with a rib along the margin of its upper side, with a picture-holder in the nature of a cross-bar, the margins of the under side of which have similar ribs, whereby the holder contacts with the shaft only at the points where the bar crosses the ribs of the shaft; whereby the surfaces of the web of the shaft and holder are protected against wear and abrasion due to sliding one over the other, substantially as specified.

12. In a stereoscope the means for uniting the margins of the two plates forming the shaft, consisting in the raised rim and transversely-turned flange-lip of the inner plate edge, in combination with the overlapping lip of the edge of the outer plate, the latter lip being bent outwardly from its web, then across and over the edge of the inner lip, thence around the latter so that its edge closes firmly into the angle of the inner plate formed by the outward bend of the inner lip; whereby the inner lip acts as a stiffening-arc within the tube formed by the curvature of the outer lip, substantially as described.

701,527. STEREOSCOPE. HAWLEY C. WHITE and HARRIS C. WHITE, North Bennington, Vt., assignors to E. C. White Co., North Bennington, Vt., a Corporation of Vermont. Filed Sept. 24, 1901. Serial No. 70,287. (No model.)

Claim.—1. A metallic stereoscope-shaft consisting of an upper and an under plate and united at their margins by an interlocking joint; and separated at their intermediate portions, and an interposed spring which is adapted to distend the two plates.

2. A metallic stereoscope-shaft consisting of an upper and an under plate, connected at their edges by a loose interlocking joint, and an interposed spring adapted to distend the two plates.

3. A metallic stereoscope-shaft consisting of an upper and an under plate, connected at their edges by an interlocking joint, and an interposed metallic spring adapted to distend the two plates.

4. A metallic stereoscope-shaft consisting of an upper and an under plate, connected at their edges by a loose interlocking joint, and an interposed metallic spring-plate, the longitudinal axis of which bears against the middle of one plate, and the parallel margins of which bear against the other plate.

5. A metallic stereoscope-shaft consisting of an upper and an under plate, one of which is provided with a central axial inward depression, a plate-spring having a corresponding central axial depression which fits over the depression of said plate, both upper and under plates and the spring-plate connecting along a longitudinal median line.

6. The combination in a stereoscope-shaft of the upper plate, under plate and an interposed spring-plate, the edges of the upper and under plates being united by a marginal joint adapted to permit slight movement of one member upon the other perpendicularly to the plane of the shaft as a means for obviating elastic rigidity.

7. In a picture-holder the combination with the shaft of a cross-bar made from sheet metal having a longitudinally-convex depression opposite where the bar crosses the shaft which is covered with a non-abrasive substance and projects sufficiently beyond the plane of the highest portions of the cross-bar where it lies over the shaft to break contact between the opposed metal surfaces of the shaft and cross-bar, substantially as specified.

8. The combination with a stereoscope-shaft, of a metallic picture-holder having a spring-clamp and cross-bar, whereof the bar has a convex cushioned depression where it crosses the shaft and the clamp has springs provided with cushioned tips or pads to bear against the under side of the shaft, substantially as specified.

701,528. SELVAGE-HEDDLE MOTION. JAMES WILKINSON, Fall River, Mass. Filed Oct. 8, 1901. Serial No. 77,622. (No model.)

(Name.—) In a selvage-motion for looms, the combination of a pick-up shaft; a cam-shaft; two adjacent sprocket-wheels, one having a diameter twice as great as that of the other, said wheels being mounted on the pick-up shaft; a sprocket-wheel having the same diameter as the larger sprocket-wheel on the pick-up shaft; a chain to engage the sprocket-wheel on the cam-shaft, and either of the two different-sized sprocket-wheels on the pick-up shaft; a cam fixed on said cam-shaft; selvage-heddles; selvage-treadles connected with said selvage-heddles, and operated by said cams.

701,529. PEANUT-MARVINTER. CHARLES E. WYCKOFF, Fort Leno, Va. Filed July 12, 1901. Serial No. 68,954. (No model.)

Claim.—1. Is a machine for harvesting peanuts and the like, comprising elevator spaced apart transversely, and an agitator-bar located in the space formed between the elevators for imparting a vibratory movement to the article being harvested, substantially as set forth.

2. In a machine for harvesting peanuts and the like, comprising ele-

vators transversely spaced, and a shaker-bar arranged in the said space and provided at its upper end with a curved portion projecting beyond the delivery end of the elevators to push the vines and peanuts therefrom, substantially as set forth.

3. In a machine for harvesting peanuts and the like, transversely-spaced elevators, means for imparting a vibratory movement thereto, and a shaker-bar located in the space formed between the elevators, substantially as set forth.

4. In combination, a main frame, an elevator-frame telescoped to the main frame and having longitudinal slots, and a crank-shaft journaled to the main frame and having its crank portion operating in the slots of the elevator-frame, substantially as set forth.

5. In combination, a main frame, an elevator-frame longitudinally movable with reference to the main frame, an endless elevator, supports for the said elevator applied to the main and elevator frames, and means for moving the frames longitudinally with reference to each other to effect a tightening or loosening of the elevator, substantially as set forth.

6. In combination, a shaft, an elevator-frame mounted to turn upon said shaft, an endless elevator, supports for the endless elevator mounted upon the aforesaid shaft and elevator-frame, and means for effecting a longitudinal movement of the elevator-frame, the same consisting of corresponding irons, adjusting means for relatively moving the irons, and fastening means for securing the irons in an adjusted position, substantially as set forth.

7. In combination, a shaft, an elevator-frame, a cross-bar having bent ends mounted upon the shaft, said cross-bar having slotted widened portions, one of the widened portions having an end portion bent, brackets secured to the elevator-frame, nut-screws mounted in the said bent ends, fastenings for securing the brackets in an adjusted position, an endless elevator, and supports for said elevator applied to the aforesaid shaft and to the elevator-frame, substantially as set forth.

8. In a harvester of the character described, and in combination with the elevator, actuating means therefor including a clutch, and means for raising and lowering the elevator, a shipper-lever, and a trip automatically actuated by the raising and lowering of the elevator to automatically throw the operating mechanism into and out of gear, substantially as set forth.

9. In combination, an elevator, means for raising and lowering the same, an actuating mechanism including a clutch, a shipper-lever in engagement with the clutch and mounted independently of the elevator-frame and having a part to be engaged by a portion of the elevator-frame to effect a making and a breaking of the clutch automatically by a raising and lowering of the elevator, substantially as set forth.

10. In combination, an elevator adapted to be raised and lowered, elevator-actuating mechanism including a clutch, and a shipper-lever for the clutch mounted independently of the elevator and having a cam-trip for cooperation with the elevator to effect an automatic making and breaking of the clutch, substantially as set forth.

701,530. LOCK-OUT. JOHN L. ALGER, Medford, Mass. Filed Mar. 5, 1902. Serial No. 68,772. (No model.)

Claim.—1. A lock-out member comprising a base and a conical extension having a bore and slotted from end to end, said slot extending in a direction diagonal to the bore.

2. A lock-out member comprising a base and a conical extension having a screw-threaded bore and having a diagonal slot extending from end to end and in a direction generally opposite to the extension of the screw-thread.

3. A lock-out member comprising a base and a conical extension having a bore and slotted from end to end, said slot being inclined to the median plane of the member, whereby a biting edge and an expanding wedge are formed on the respective faces of said slot.

4. A lock-out member comprising a base and a conical extension having a bore and furnished with a slot diagonal to bore and inclined to the median plane thereof.

5. The combination with the member 5 having the conical socket 6, of the member 6, having the base 11 and the extension 12 and furnished with the slot 14, having the edge 15 and the surfaces 16 and 17, as and for the purpose described.

701,531. ROTARY ENGINE. WILLIAM F. BAKER, Braintree, Mass. Filed July 5, 1901. Serial No. 67,122. (No model.)

Claim.—1. In a rotary engine, the combination with a hollow base having side bearings and cylinder-heads concentric with the bearings, of a piston having a shaft disposed in the bearings, the piston lying between the heads, the piston and heads having equal radii, and an arcuate plate fitted against the outer face of the piston and cylinder-heads and having yieldable connection with the latter, said plate having an inlet-passage therethrough and the piston having pockets to receive from the inlet-passage.

2. A rotary engine comprising a hollow base having cylinder-heads and bearings therein, a piston fitted between the heads and having a shaft journaled in the bearings, the lower side of the piston being exposed within the base, a cylinder-plate fitted against the outer face of the piston and cylinder-heads, spring pressure devices for holding the plate yieldably against the piston to take up wear, a fixed plate-covering and spaced from the remaining portion of the upper face of the piston, said cylinder-plate having an inlet-passage therethrough and the piston having pockets in line with the passage, and a feed-pipe connected with the passage.

3. A rotary engine comprising a rotatable piston, a base in which the piston is mounted and partly contained, said piston having a central series of pockets and an annular groove at each side thereof and annular flanges at the outer sides of the grooves, and a cylinder-plate fitted against the piston and having arcuate flanges engaged with the grooves, the flanges having longitudinally-extending channels provided with packing projecting therefrom, and adjustable means for holding the plate yieldably in contact with the piston.

701,582. DOUBLE OR STEP LADDER. EMILE BARDON, Bangor, France. Filed May 31, 1901. Serial No. 62,663. (No model.)

Claim.—A step-ladder comprising the limbs a, b, pivoted together, a platform A pivoted at one of its ends to one of the limbs, a support c on the other limb upon which the platform rests at or near its free end, said support when the ladder is folded moving toward the pivoted end of the platform to allow the said platform to fall at its free end, a tool-box, arms j connecting the free end of the platform with the tool-box and arms k connecting the tool-box with the ladder at or near its upper end, the said arms and tool-box moving downwardly when the platform falls at its free end upon the folding of the step-ladder, substantially as described.

701,583. DRIVING MECHANISM FOR MOTOR-VEHICLES. CLARENCE C. BRANWELL, Hydeport, Mass. Filed Sept. 14, 1898. Serial No. 730,401. (No model.)

Claim.—In a motor-vehicle, a driving wheel or wheels, a motor, intermediate power-transmitting means, including a worm and meshing worm-gear, a fly-wheel rotatable with the worm, a brake for said fly-wheel, controlling means for the motor, and actuating connections between said means and the brake, to govern the latter.

701,584. PICKER-OPERATING MECHANISM FOR SWIVEL-LOOMER. FRED EDWIN PATTERSON, N. J., assignor to Joseph Wadsworth, Paterson, N. J. Filed Jan. 16, 1902. Serial No. 89,801. (No model.)

Claim.—1. In a swivel-loom, the loom-frame, a rock-shaft mounted therein, a picking-stick pivotally secured to said frame, a lever-arm secured to said rock-shaft and a lug-strap connecting said lever and picking-stick, in combination with a shoe-block also secured to said rock-shaft and having a raceway therein, a shoe adapted to slide therein, a spring to hold said shoe in its normal position, and means for temporarily withdrawing and holding said shoe from and out of its normal position, substantially as set forth.

2. In a swivel-loom, a rock-shaft, a shoe-block secured to same and provided with a raceway therein, in combination with a shoe adapted to slide therein, means therein to hold said shoe normally in the path of revolving picking-balls, and means for temporarily withdrawing and holding said shoe from, and out of its normal position, substantially as set forth.

3. In a swivel-loom, the combination with the picking-stick, provided with a picking-arm carrying picking-balls, of the rock-shaft, a shoe-block secured thereto having a raceway in it and a sliding shoe adapted to reciprocate therein, means to hold said shoe normally in the path of the picking-balls to rock the rock-shaft and means for temporarily withdrawing and holding said shoe from, and out of its normal position, substantially as set forth.

701,585. DOUBLE-BELLOWS ACTION FOR PNEUMATIC PIANO-PLAYERS. THOMAS F. BROWN and PETER WILK, Worcester, Mass. Filed June 29, 1901. Serial No. 64,693. (No model.)

Claim.—1. In an automatic piano-player, the combination with power-pneumatics and suitable key-operating instrumentalities, of a low-tension chamber communicating with said pneumatics, a high-tension chamber independent of said low-tension chamber communicating with said pneumatics, a single valve controlling the ports leading from said low and high tension chambers to each of said power-pneumatics, a low-tension bellows communicating with said low-tension chamber, and a high-tension bellows communicating with said high-tension chamber, and feeders for said bellows.

2. In an automatic piano-player, the combination with power-pneumatics and suitable key-operating instrumentalities, of a low-tension chamber communicating with said pneumatics, a high-tension chamber independent of said low-tension chamber communicating with said pneumatics, a single valve controlling the communication of said tension-chambers

with each of said power-pneumatics, a low-tension bellows communicating with said low-tension chamber, a high-tension bellows communicating with said high-tension chamber, a tracker having ducts controlling the valves which regulate the communication of said high and low tension chambers with the power-pneumatics, and feeders for the high and low tension bellows.

3. In an automatic piano-player, the combination with power-pneumatics and suitable key-operating instrumentalities, of a low-tension chamber communicating with said pneumatics, a high-tension chamber independent of said low-tension chamber communicating with said pneumatics, a single valve controlling the communication of said tension-chambers with each of said pneumatics, a low-tension bellows communicating with said low-tension chamber, a high-tension bellows communicating with said high-tension chamber, and a tracker having separate ducts for controlling the valves which regulate the communication of said low-tension chamber and said high-tension chamber with said power-pneumatics.

4. In an automatic piano-player, the combination with a low-tension bellows, of a high-tension bellows independent thereof, separate feeders for each of said bellows, a low-tension vacuum-chamber, a high-tension vacuum-chamber, means for cutting off communication between said diaphragm-chambers and said high and low tension chambers, and power-pneumatics in communication with said diaphragm-chambers.

5. In an automatic piano-player, the combination with a low-tension bellows, of a high-tension bellows independent thereof, separate feeders for said bellows, a low-tension vacuum-chamber connected with said low-tension bellows, a high-tension vacuum-chamber connected with said high-tension bellows, diaphragm-chambers in communication with both of said vacuum-chambers, a single valve controlling the port between each of said diaphragm-chambers and said low and high tension chambers, and power-pneumatics in communication with said diaphragm-chambers.

6. In an automatic piano-player, the combination with a low-tension bellows, of a high-tension bellows independent thereof, feeders for said bellows, a low-tension vacuum-chamber, diaphragm-chambers in communication with said low-tension chamber through normally open valved ports, power-pneumatics having valved ports communicating with said diaphragm-chambers, a high-tension vacuum-chamber having normally closed ports leading to said diaphragm-chambers, means for cutting said low-tension chamber out of communication with said diaphragm-chambers, and putting said high-tension chamber in communication therewith.

7. In an automatic piano-player, the combination with a low-tension bellows, of a high-tension bellows independent thereof, feeders for said bellows, a low-tension vacuum-chamber, diaphragm-chambers in communication with said low-tension chamber through normally open valved ports, power-pneumatics having valved ports communicating with said diaphragm-chambers, a high-tension vacuum-chamber having normally closed ports leading to said chambers, a single valve controlling the communication of said high and low tension chambers with each of said power

pneumatics, and means for operating said valve to cut out said low-tension chamber and bring said high-tension chamber into action.

8. In an automatic piano-player, the combination with a low-tension bellows, of a high-tension bellows independent thereof, separate feeders for each of said bellows, a low-tension vacuum-chamber in communication with said high-tension bellows, a high-tension vacuum-chamber in communication with said low-tension bellows, independent diaphragm-chambers communicating with both of said vacuum-chambers, power-pneumatics, pockets separated by the diaphragm from said diaphragm-chambers, a tracker having ducts communicating with the pockets of said diaphragm-chambers, valve-controlled ports leading from said diaphragm-chambers to said pneumatics, and means to cut out said low-tension chamber and simultaneously throw said high-tension chamber into action.

9. In an automatic piano-player, the combination with a low-tension bellows, of a high-tension bellows independent thereof, separate feeders for said bellows, a low-tension vacuum-chamber in communication with said low-tension bellows, a high-tension vacuum-chamber in communication with said high-tension bellows, a series of separate diaphragm-chambers having valved ports leading to both of said tension-chambers, a series of power-pneumatics communicating with said diaphragm-chambers, means for selecting any one of said diaphragm-chambers and power-pneumatics for action, and means for cutting out said low-tension vacuum-chamber and throwing said high-tension chamber into communication with any of said diaphragm-chambers so selected.

10. In an automatic piano-player, the combination with a low-tension bellows, of a high-tension bellows independent thereof, separate feeders for said bellows, means for operating said feeders, a low-tension vacuum-chamber in communication with said low-tension bellows, a high-tension vacuum-chamber in communication with said high-tension bellows, a series of diaphragm-chambers in communication with both of said vacuum-chambers, a single valve controlling the ports leading from each of said diaphragm-chambers to said vacuum-chambers, power-pneumatics having valved ports leading to said diaphragm-chambers, a tracker provided with ducts through which said power-pneumatic valves are controlled, said tracker having independent ducts through which the valved ports leading from said diaphragm-chambers to said vacuum-chambers are controlled.

11. In an automatic piano-player, the combination with a low-tension bellows, of a high-tension bellows independent thereof, feeders for said bellows, a low-tension vacuum-chamber in communication with said low-tension bellows, a high-tension vacuum-chamber in communication with said high-tension bellows, diaphragm-chambers having valved ports leading to both of said vacuum-chambers, power-pneumatics having valved communication with said diaphragm-chambers, and a tracker controlling said valved connections between the diaphragm-chambers and their power-pneumatics, and between said diaphragm-chambers and said low and high tension vacuum-chambers.

12. In an automatic piano-player, the combination with key-operating instrumentalities, of a low-tension bellows and a high-tension bellows, adapted to be placed in communication with said key-operating instrumentalities, valves for controlling the ports leading from said bellows, valves for controlling the ports leading to the key-operating instrumentalities, and a tracker having ducts for controlling the valves which regulate the action of said key-operating instrumentalities, and separate ducts for regulating the valves which control the said high and low tension bellows.

13. In an automatic piano-player, the combination with key-operating instrumentalities, of a low-tension bellows, a high-tension bellows, power-pneumatics connected through valved ports with said high and low tension bellows independently of each other, valves in said ports, a tracker having selecting-ducts for controlling the valves which regulate the action of said power-pneumatics, said tracker having accentuation-ducts for controlling the valves which regulate the action of said high-tension bellows.

14. In an automatic piano-player, the combination with key-operating instrumentalities, of a low-tension bellows, a high-tension bellows, power-pneumatics independently connected through valved ports with said high and low tension bellows, valves in said ports, a tracker having selecting-ducts for controlling the valves which regulate the action of said power-pneumatics, said tracker having accentuation-ducts for controlling the valves which regulate the action of said high-tension devices on one or more of said power-pneumatics.

15. In an automatic piano-player, the combination with high and low tension wind-chests, of the sound-producing instrumentalities operable from either of said chests, a tracker having a series of note-selecting ducts, a series of accentuation-ducts and a duct-board having a series of accentuation-ducts communicating with the chordal accentuation-ducts and each provided with a plurality of branches whereby two or more of the sound-producing instrumentalities are controlled from a single accentuation-duct.

16. A tracker for automatic piano-player having a series of note-selecting ducts therein and an accentuation-duct, combined with a duct-

board having a plurality of passages or ducts in communication with said atmosphere-duct.

17. In an automatic piano-player, the combination with high and low tension wind-chests, of power-pneumatics operable from either of said wind-chests, valves for controlling the action of the high and low tension wind-chests, valves for controlling the action of the power-pneumatics, a tracker provided with ducts to select and bring into action the valves that control said power-pneumatics, said tracker being provided with separate ducts for controlling the valves that regulate the action of said high-tension wind-chest on a plurality of said pneumatics.

18. In an automatic piano-player, the combination with key-operating instrumentalities, of power at pneumatic, diaphragm-chambers having valved communication with said power-pneumatics, a low-tension chamber normally in communication with said diaphragm-chambers, a high-tension chamber, controlling means for cutting out said low-tension chamber and throwing said high-tension chamber into communication with said diaphragm-chambers, a tracker, connections between said tracker and said diaphragm-chambers, and connections between said tracker and said controlling means for the low and high tension chambers.

701,586. ELECTRIC PUMPING-ENGINE. OVEN BERMAN, Elzing, Sweden, assignor to De Laval Steam Turbine Company, a Corporation of New Jersey. Filed Oct. 2, 1901. Serial No. 74,003. (No model.)

Claim.—1. The combination in an electric pumping-engine of a vehicle, an inclosing drum or cylinder supported on said vehicle and divided into two compartments, an electric motor disposed in one compartment and a rotary pump actuated thereby in the other compartment, and on the exterior of said cylinder means for connecting suction and delivery pipes to said pump-compartment and means for connecting a source of electric current to said motor.

2. The combination in an electric pumping-engine of a vehicle, an inclosing drum or cylinder supported on said vehicle and divided into two horizontally-closed compartments, each provided with an opening for allowing access to its interior and with means for closing said openings, an electric motor disposed in one compartment and a rotary pump actuated thereby in the other compartment, and on the exterior of said cylinder means for connecting suction and delivery pipes to said pump-compartment and means for connecting a source of electric current to said motor.

3. The combination in an electric pumping-engine of an inclosing cylinder or drum divided into two compartments, an electric motor in one of said compartments, a rotary pump in the other compartment, a shaft extending through both compartments and carrying the armature of said motor and the wheel of said pump, means for connecting said motor and said pump respectively to sources of electric current and liquid supply, and means exterior to said drum for regulating the tightness of the joint between said shaft and the partition dividing said compartments.

701,587. BAG-FASTENER. GEORGE M. BURET, Cumberland, Md. Filed June 21, 1901. Serial No. 66,476. (No model.)

Claim.—The combination with a bag or sack, of a permanent non-removable fastener for securing the gathered mouth or neck of the bag and rendering the same non-refillable, said fastener consisting of a staple having the terminal portions thereof flattened and sharpened by beveling on opposite sides, the extremities of said terminal portions, in the act of applying the fastener, being recurved and extended convergently inward, the fastener being compressed tightly around the neck of the bag and the sharpened terminals thereof being simultaneously brought together and driven into the sack under pressure, substantially as described.

701,588. NASAL SHIELD. THOMAS CARLSON, Kansas City, Mo. Filed Sept. 18, 1901. Serial No. 73,533. (No model.)

Claim.—1. In a nasal shield, the combination of two open-ended tubes, respectively provided with exteriorly-projecting plates, a bridge connecting the tubes, an absorbent pad surrounding each tube in contact with the plate, a removable plate surrounding each tube in contact with the pad and opposed to the first-named plate, and a cap applied to each tube to hold the removable plate in position and to cause it to clamp the pad, said cap being provided with a diaphragm adapted to strain out the dust while it allows the air to pass through the tube.

2. In a device of the class described, the combination of two tubular parts, an outwardly-bowed bridge-piece connecting said parts, two opposing plates surrounding each tube, absorbent material held between the plates and protruding therefrom, and a cap applied to each tube and provided with a gauze diaphragm for the purpose set forth.

3. In a device of the class described, the combination of two open-ended, cylindrical parts, a bow-shaped bridge connecting said parts, two opposing plates mounted on each cylinder, absorbent pads held by the plates, and a cap applied to each cylinder and provided with a gauze diaphragm for the purpose set forth.

4. The combination of two tubular parts, a bridge connecting said parts, absorbent pads mounted on the tubular parts, means for holding the pads in place, and a gauze diaphragm applied to each part for the purpose set forth.

5. The combination of two cylinders, a plate surrounding each cylinder, a pad engaging the plate, another plate surrounding the cylinder on the opposite side of the pad, and a screw-cap applied to the cylinder and made to engage the adjacent plate, the cap being provided with a wire-gauze diaphragm.

6. The combination of two exteriorly-threaded cylinders, a bridge connecting said cylinders, a concavo-convex plate applied to each cylinder and made fast thereto, its outer edges being serrated or toothed, an absorbent pad applied to the plate around each cylinder, a similar loose plate applied to each cylinder and engaging the pad opposite the first-named plate, and an interiorly-threaded cap screwed upon each cylinder to engagement with the loose plate, said cap being provided with a wire-gauze diaphragm.

701,589. INSULATOR-PIN MACHINE. AMEL D. CATTIN, Chattanooga, Tenn. Filed May 27, 1901. Serial No. 62,002. (No model.)

Claim.—1. An insulator-pin machine, comprising spindle and means for rotating them, centers-forming cutters, a thread-cutting device, and means for imparting a more rapid rotation when the thread-cutting device is in operation.

2. In an insulator-pin machine, the combination with the cutting device, of a pivoted frame, means therein for supporting the pin-blank and causing it to rotate, and means whereby the speed of rotation of the blank may be increased at the beginning of the threading operation, and suitable threading devices likewise carried by the movable frame.

3. In an insulator-pin machine, the combination with the frame, the cutting devices for turning the pin-blank to the proper shape, a movable frame pivoted to the main frame, supporting-centers in said movable frame for holding the pin-blank, one of said centers being carried on the end of a threaded spindle, threading device for imparting the thread to the pin, means for causing the threading device to operate in correspondence with the threaded spindle, and means for causing the threaded spindle to run at a higher speed in threading than in turning.

4. In an insulator-pin machine, the combination with the main frame, of centers for turning the pin, a movable frame pivoted to the main frame, centers for supporting the pin-blank, one of which centers is carried on the end of a threaded spindle, gearing for driving said spindle which includes a clutch device for fast and slow speeds, a tracer-pin engaging the threaded spindle, and the threading-tool, the two being carried by a common shiftable rod, and means whereby said rod may be adjusted to place the threading device in operative position and simultaneously to adjust the clutch for high speed in threading.

5. In an insulator-pin machine, the combination with the main frame and the turning-cutter supported thereon, of a movable frame pivotally supported on the main frame, adjustable pin-blank-containing device, one of which is carried by a threaded shaft, a clutch on said shaft, speed-changing gears likewise on the shaft, a threading implement which is operated from the shiftable threaded shaft and means whereby the speed of the threaded shaft will be accelerated when the threading implement is in connection.

6. In an insulator-pin machine, the combination with the main frame, and means carried thereby for shaping the blank to the proper form, of a swinging frame and centering device therein, one of which is carried by a threaded spindle, a clutch-gear on said shaft, the gearing arrangement for driving the gears at different speeds, a threading implement, an end-wise-movable spring-provided shaft carrying it, a tracing-pin on said shaft engaging the threaded spindle, a shipper-bar for operating the clutch, an angular slide engaging the shipper-bar, and a lever on the threading-tool shaft which connects with the angular bar.

7. The combination with the main frame, a cutter therein for shaping the blank to the proper form, supporting devices for the blank, means for driving them at different speeds, a threading-tool, a spring-provided rod carrying it, said rod having a handle, a lever fixed on said rod, a clutch for controlling the means for driving the device that supports the blank, a shipper-bar arranged to operate said clutch, an angular slide-bar engaging an inclined groove in the shipper-bar and being itself engaged by the aforesaid lever.

701,540. OLEVIA. JAMES H. CHIMMERT and WILLIAM TYRE, St. Louis, Mo. Filed Mar. 15, 1902. Serial No. 64,554. (No model.)

Claim.—The combination with parallel jaws, of a clevis having means for the adjustable connection of a draft-chain and provided with devices whereby it can be attached to jaws of any width, consisting of a stationary leg on the clevis to engage with one jaw, ribs along the rear edge of the clevis, and a block adapted to engage with the other jaw and having flanges engaging with the ribs on the clevis.

701,541. GRASS AND DITCH LINES. JAMES H. CHIMMERT, St. Louis, Mo. Filed Mar. 17, 1902. Serial No. 64,556. (No model.)

Claim.—1. A grass and ditch liner comprising a beam adapted to be attached to a hand-car, an adjustable beam pivoted to the beam, a trailing arm having a line-marker at the free end thereof and attached to an end of the beam, a head adjustably attached to the beam, and a controlling-lever attached to the head.

2. The combination with a hand-car, of a grass and ditch liner comprising a beam rigidly attached to the forward end of the car-body, a hori-

zontal beam pivotally and adjustably connected to the beam and having a trailing arm provided with a line-marker whereby lines may be cut into the ground at the side of the car, and a controlling-lever adjustably attached to the beam.

3. In a grass and ditch liner, the combination with the car, of the beam attached to the forward end of the car, the fixed hinge parts attached to the beam, the companion hinge parts connected to the fixed hinge parts the beam adjustably attached to the companion hinge parts, the head adjustably attached to the beam, the lever pivoted to the head and having the head adapted to engage the beam, the movable weight on said lever, the trailing arm attached to said beam, and the line-marker connected to the free end of said arm, substantially as and for the purposes set forth.

701,542. REGULATOR FOR STEAM-GENERATORS. THOMAS CLARKSON, London, England. Filed July 30, 1899. Serial No. 724,547. (No model.)

Claim.—1. In a regulator for steam-generators, the combination of two tubular metallic members having different coefficients of expansion and adapted to be connected to the generator to permit a heated fluid from the generator to flow through them, a rigid base supporting one end of each member and a movable connection for the other end of each member, a lever pivoted adjacent to the said members, a projection on the lever adapted to be engaged by said connection and adjustable in relation thereto, a device for controlling the flow of fluid to the generator, and connections between the lever and each device, substantially as and for the purpose specified.

2. In a regulator for steam-generators, the combination of two tubular metallic members having different coefficients of expansion and adapted to be connected to the generator to permit a heated fluid from the generator to flow through them, a rigid base to which one end of each member is attached, a movable connection for the other ends of the members, a lever pivoted adjacent to the said members, a projection on the lever adapted to be engaged by said connection and adjustable in relation thereto.

to, a device to control the feed of fuel to the generator, and connections between the lever and such device, substantially as and for the purpose specified.

3. In a regulator for steam-generators, the combination of the fixed support, A, tubular metallic members B and D, secured at one end to the support A and having different coefficients of expansion and adapted to be connected to the generator to permit a heated fluid from the generator to flow through them, a movable connection C for the other ends of the tubular members, plates F secured to the support A and projecting therefrom, a lever G pivoted between the outer ends of said plates, a projection G' supported on the said lever to be engaged by the connection C, means to adjust said projection relatively to the connection C, a valve to control the feed of fuel to the generator, connections between the lever G and said valve, and means to move the valve and lever in a direction opposite to that in which they are moved by the connection C, substantially as and for the purpose set forth.

701,543. VARIABLE-SPEED GEAR. FRANK B. COHEN, New York, N. Y., assignor to Hill-Sement-Pond Company, Jersey City, N. J. Filed Mar. 31, 1902. Serial No. 160,776. (No model.)

Claim.—1. In variable-speed gears, the combination, substantially as set forth, of a shaft, a series of diversely-sized gears fast thereon, a splined shaft, a plurality of gears splined thereon, a double-armed tumbler sliding with said splined gears, a plurality of diversely-sized gears carried by said tumbler and driven from one of the splined gears and adapted for engagement with said diversely-sized gears, a second plurality of gears carried by the tumbler and driven from another one of said splined gears and adapted for engagement with said diversely-sized gears, and means for adjusting and locking the tumbler.

2. In variable-speed gears, the combination, substantially as set forth, of a shaft, a series of diversely-sized gears fast thereon, a splined shaft, a plurality of gears splined thereon, a double-armed tumbler sliding with said splined gears, a plurality of diversely-sized gears carried by said tumbler and driven from one of the splined gears and adapted for engagement with said diversely-sized gears, a second plurality of gears carried by the tumbler and driven from another one of said splined gears and adapted for engagement with said diversely-sized gears, a casing provided with an opening for a projecting portion of the tumbler, an upper and a lower longitudinal series of stops arranged at the margins of said opening and adapted to determine the angular and longitudinal position of the tumbler, and means for adjusting and locking the tumbler.

701,544. GUIDE FOR PUNCHING-PRESS. THOMAS CUNLEY and JOHN B. CUNLEY, Pittsburg, Pa. Filed Aug. 30, 1901. Serial No. 73,961. (No model.)

Claim.—1. The combination with a punch or drill press, of a carriage, a reciprocating rod mounted on said carriage, and a series of separately-adjustable stops adapted to contact with said rod and stop the carriage at predetermined points.

2. The combination with a punch or drill press and a carriage for conveying metal into position to be operated on, of separately-adjustable stops for stopping and retaining said carriage at predetermined points and means for causing the carriage to be engaged by and disengaged from said stops.

3. The combination with a punch or drill press, of a carriage, means for holding work in position on said carriage, a series of separately-adjustable stops, for stopping said carriage at predetermined points, and a manually-operable device carried on the carriage and adapted to engage with said stops.

4. The combination with a press and a movable carriage, of a guide for stopping said carriage consisting of a rail or rod provided with adjustable stops and adapted to stop the movement of the carriage at predetermined intervals.

701,545. INKING APPARATUS FOR PRINTING-MACHINES. CHARLES F. COTTRELL, Westbury, N. Y., assignor to C. R. Cottrell & Sons Company, New York, N. Y., and Westbury, Conn., a Corporation of New Jersey. Filed Nov. 1, 1901. Serial No. 90,722. (No model.)

Claim.—1. In the inking apparatus of a printing-machine, the combination with roller-stand tops and supports to which they are hinged, of toothed sector-carrying levers one on each stand-top, a lifting-shaft and bearings therefor, pinions on said shaft one for each sector-carrying lever, and means for turning and locking said shaft, substantially as herein described.

2. In the inking apparatus of a printing-machine, the combination with roller-stand tops and supports to which they are hinged, of toothed sector-carrying levers one on each stand-top, a lifting-shaft and bearings therefor, pinions on said shaft one for each sector-carrying lever, a gear on said lifting-shaft, a hand-wheel and a pivotal support therefor, gearing between said hand-wheel and said gear on the lifting-shaft for lifting the stand-tops, a ratchet on said gear and a pawl engaging therewith for locking the stand-tops with their rollers in operative position, a ratchet-wheel carried by said hand-wheel, and a pawl engaging with the latter ratchet-wheel to lock the roller-stands in their lifted position, substantially as herein described.

3. In the inking apparatus of a printing-machine, the combination with fixed roller-stands and inking-rollers and bearings therefor in said stands, of roller-stand tops one for each side of the machine containing the bearings for ink-distributing rollers, fixed supports to which said stand-tops are directly pivoted at fixed points, lifting-plates applied within said stands under the journals at both ends of the form-rollers, and connections between each co-pivoted stand-top and the lifting-plate on the same side of the machine for operating said lifting-plates by the raising of the stand-tops, substantially as herein described.

4. In the inking apparatus of a printing-machine, the combination with roller-stands and inking-rollers and bearings therefor in said stands, of roller-stand tops containing ink-distributing rollers, fixed supports to which said stand-tops are directly pivoted at fixed points, lifting-plates applied within said roller-stands under the journals of the inking-rollers, toggles supporting said lifting-plates, means for raising said stand-tops on their hinges and connections between said co-pivoted stand-tops and toggles for operating said lifting-plates by the raising of the stand-tops, substantially as herein described.

701,546. DRYING-RACK. JOHN E. DAVIS, Chicago, Ill. Filed Aug. 12, 1901. Serial No. 71,792. (No model.)

Claim.—1. A drying-rack comprising a rod-carrier, a series of rods supported by said carrier and arranged to have the material to be dried suspended in loops below and from said rods, a feeder adapted to supply said material to said rods and to carry and support same together with one of said rods for a considerable distance immediately before reaching the point at which the loops begin to form; said feeder being adapted to carry and support said material independently of the support afforded by the rod carried therewith.

2. A drying-rack comprising a rod-carrier, a series of rods supported by said carrier and arranged to have the material to be dried suspended in loops below and from said rods, a feeder adapted to supply said material to said rods and to carry and support same together with one of said rods, in a substantially horizontally disposed plane, for a considerable distance immediately before reaching the point at which the loops begin to form; said feeder being adapted to carry and support said material independently of the support afforded by the rod carried therewith.

3. A drying-rack comprising a rod-carrier, a series of rods supported by said carrier and arranged to have the material to be dried suspended in loops below and from said rods, a feeder for said material arranged to carry and support same along with one of said rods to a point at which the loops begin to form, and means in advance of and adjoining said feeder for depressing the rods upon the carrier and preventing their dragging or shifting out of parallel relation during the formation of the loop.

4. A drying-rack comprising a rod-carrier, a series of rods supported by said carrier and arranged to have the material to be dried suspended in loops below and from said rods, a feeder for carrying said material to the rods, and means in advance of and adjoining said feeder for depressing the rods upon the carrier and preventing their dragging or shifting out of parallel relation.

5. A drying-rack comprising a rod-carrier, a series of rods supported by said carrier and arranged to have the material to be dried suspended in loops below and from said rods, a feeder for carrying said material to the rods, and a belt traveling with the carrier in advance of and adjoining said feeder for depressing the rods upon the carrier and preventing their dragging or shifting out of parallel relation.

6. A drying-rack comprising a frame having an open space extending longitudinally of same through which the material to be dried may be passed in suspended loops; a conveyor extending along each side of said space at the upper part; a series of rods supported and carried by said conveyors and arranged to support said loops; a conveyor below said space adapted to receive said rods after they have traversed the upper conveyor, and to return same in parallel relation toward the end of said rods at which said material is received on said upper conveyor; a rod-storage extending along and curving upwardly beyond the forward end of said lower conveyor; a stop for said rods at the forward end of said rod-storage; said lower conveyor being arranged to advance

relatively to the rods held in said storage and to crowd said rods against each other and into said upwardly-curved part, toward said stop; and a pick-up intersecting the upwardly-curved end of said rod-storage and adapted to engage the rods in said storage, one at a time, and deposit same in parallel relation upon the upper conveyors; and means for feeding said material upon the rods near the upper part of said pick-up.

7. A drying-rack comprising a rod-carrier, a series of rods supported by said carrier and arranged to have the material to be dried suspended in loops below and from said rods; a pair of opposed conveyor-belts passing downwardly near each side of the discharge end of said carrier and adapted to engage said rods and prevent same from tilting or shifting out of parallel relation at the time of their discharge from said carrier; a lower conveyor adapted to receive said rods from said conveyor-belts and return same toward the receiving end of said carrier, and a pick-up adapted to receive the rods from said lower conveyor and deposit same in parallel relation upon the receiving end of said carrier.

8. A drying-rack comprising a rod-carrier, a series of rods supported by said carrier and arranged to have the material to be dried suspended in loops below and from said rods; a pair of opposed conveyor-belts passing downwardly near each side of the discharge end of said carrier and adapted to engage said rods and prevent same from tilting or shifting out of parallel relation at the time of their discharge from said carrier.

9. A drying-rack comprising a rod-carrier, a series of rods supported by said carrier and arranged to have the material to be dried suspended in loops below and from said rods; means for supporting the material independently of said rods at the discharge end of said carrier; and a pair of opposed conveyor-belts located toward each side of the discharge end of said carrier adapted to engage said rods and prevent same from tilting or shifting out of parallel relation at the time of their discharge from said carrier and until the rods are free from contact with said material.

10. A drying-rack comprising a rod-carrier, a series of rods supported by said carrier and arranged to have the material to be dried suspended in loops below and from said rods; means for supporting the material independently of said rods at the discharge end of said carrier; a conveyor-belt adapted to receive the rods at the time of their discharge from the carrier; and means for urging the rods against said conveyor-belt to prevent same from tilting or shifting out of parallel relation at the time of their discharge from said carrier and until the rods are free from contact with said material.

701,547. WELL-BORING APPARATUS. JOHN T. DAVIS, San Francisco, Cal. Filed Apr. 2, 1901. Serial No. 64,102. (No model.)

Claim.—1. In a well-boring apparatus, a well-casing, a hollow boring-tube therein composed of sections, a boring-head carried by said tube, a conveyor-flight and sectional conveyor-tube within the boring-tube, a gear-

wheel connected by a flange and groove with the upper section of the boring-tube and means whereby sections may be interposed in the boring-tube and conveyor-tube consisting of the coupling D having a central bore to receive the sections of the conveyor-tube and annular internally-threaded sockets opening upwardly and downwardly to receive the boring-tube sections, substantially as described.

2. In a well-boring apparatus, the upper section of well-casing, a shoe mounted thereon, and having a circular track, an upper section of drill-rod tubing, rollers carried thereby and traveling upon said track, a gear-wheel held against vertical movement with the drill-tube and the well-casing having a feathered and grooved communication with said section of drill-tubing, whereby said upper sections of well-casing and of drill-tubing are permitted to move vertically in both directions, and means for holding the well-casing with its shoe up against the said rollers.

3. In a well-boring apparatus, a driving-gear, a section of drill-rod feathered thereto, a collar secured to said section and having rollers, a section of well-casing, a circular track supported thereby, a driving-shaft and counterbalance means connected with the well-casing to hold it with its circular track up against the rollers carried by the drill-rod; whereby the said well-casing and drill-rod can sink automatically as the boring progresses, and can also be raised to permit of the insertion of successive lower sections, said driving-gear being held against vertical movement with the drill-rod and well-casing.

701,548. FLUSHING APPARATUS. CHARLES E. DAY, Inventor.
Orange, N. J. Filed Dec. 12, 1901. Serial No. 68,285. (No model.)

Claim.—1. A flushing apparatus or the like, comprising, a tank, a water-outlet in the bottom of the tank provided with a valve-seat, a vertical stem and a valve-disk thereon movably arranged above said valve-seat, a pull device for raising said stem, a clamping device and means on said stem adapted to be brought in sliding and holding engagement with said clamping device, for holding said stem in its raised position while the level of the water is being lowered, and means actuated by the receding water for releasing said stem from its raised position with the said clamping device to close said water-outlet, substantially as and for the purposes set forth.

2. A flushing apparatus or the like, comprising, a tank, a water-outlet in the bottom of the tank provided with a valve-seat, a vertical stem and a valve-disk thereon movably arranged above said valve-seat, a pull device for raising said stem, a clamping device for holding said stem in its raised position while the level of the water is being lowered, and means actuated by the receding water for releasing said stem from its raised position with the said clamping device to close the said water-outlet, consisting, essentially, of a float and a float-arm adapted to be brought in engagement with a part of the said stem, substantially as and for the purposes set forth.

3. A flushing apparatus or the like, comprising, a tank, a water-outlet in the bottom of the tank provided with a valve-seat, a vertical stem and a valve-disk thereon movably arranged above said valve-seat, a pull device for raising said stem, a clamping device and means on said stem adapted to be brought in sliding and holding engagement with said clamping device, for holding said stem in its raised position while the level of the water is being lowered, means actuated by the receding water for releasing said stem from its raised position with the said clamping device to close the said water-outlet, and a water-inlet valve connected with said tank for admitting water into said tank when the outlet is closed, substantially as and for the purposes set forth.

4. A flushing apparatus or the like, comprising, a tank, a water-outlet in the bottom of the tank provided with a valve-seat, a vertical stem and a valve-disk thereon movably arranged above said valve-seat, a pull device for raising said stem, a clamping device for holding said stem in its raised position while the level of the water is being lowered, means actuated by the receding water for releasing said stem from its raised position with the said clamping device to close the said water-outlet, consisting, essentially, of a float and a float-arm adapted to be brought in engagement with a part of said stem, and a water-inlet valve connected with said tank, the valve being connected with and operated by the said float-arm, substantially as and for the purposes set forth.

5. A flushing apparatus or the like, comprising, a tank, a water-outlet

in the bottom of said tank, a valve-seat in said outlet provided with a valve-disk, a guiding means in said valve-seat, a vertical stem and a valve-disk thereon, the lower portion of said stem extending down between the said guiding means, a pull device for raising said stem, a bracket provided with an opening in which the upper and portion of said stem is movably arranged, spring clamping-fingers extending from said bracket, an enlargement on said stem adapted to be brought in holding engagement with said fingers for holding said stem in its raised position while the level of the water is being lowered, substantially as and for the purposes set forth.

6. A flushing apparatus or the like, comprising, a tank, a water-outlet in the bottom of said tank, a valve-seat in said outlet provided with a valve-disk, a guiding means in said valve-seat, a vertical stem and a valve-disk thereon, the lower portion of said stem extending down between the said guiding means, a pull device for raising said stem, a bracket provided with an opening in which the upper and portion of said stem is movably arranged, spring clamping-fingers extending from said bracket, an enlargement on said stem adapted to be brought in holding engagement with said fingers for holding said stem in its raised position while the level of the water is being lowered, and means actuated by the receding water for releasing said stem from its raised position to close the said water-outlet, substantially as and for the purposes set forth.

7. A flushing apparatus or the like, comprising, a tank, a water-outlet in the bottom of said tank, a valve-seat in said outlet provided with a valve-disk, a guiding means in said valve-seat, a vertical stem and a valve-disk thereon, the lower portion of said stem extending down between the said guiding means, a pull device for raising said stem, a bracket provided with an opening in which the upper and portion of said stem is movably arranged, spring clamping-fingers extending from said bracket, an enlargement on said stem adapted to be brought in holding engagement with said fingers for holding said stem in its raised position while the level of the water is being lowered, and means actuated by the receding water for releasing said stem from its raised position to close the said water-outlet, consisting, of a projection extending from the side of said stem, and a float and float-arm adapted to be brought in engagement with said projection, substantially as and for the purposes set forth.

8. A flushing apparatus or the like, comprising, a tank, a water-outlet in the bottom of said tank, a valve-seat in said outlet provided with a valve-disk, a guiding means in said valve-seat, a vertical stem and a valve-disk thereon, the lower portion of said stem extending down between the said guiding means, a pull device for raising said stem, a bracket provided with an opening in which the upper and portion of said stem is movably arranged, spring clamping-fingers extending from said bracket, an enlargement on said stem adapted to be brought in holding engagement with said fingers for holding said stem in its raised position while the level of the water is being lowered, and means actuated by the receding water for releasing said stem from its raised position to close the said water-outlet, consisting, of a projection extending from the side of said stem, and a float and float-arm adapted to be brought in engagement with said projection, and a water-inlet valve connected with said tank for admitting water into said tank when the outlet is closed, substantially as and for the purposes set forth.

9. A flushing apparatus or the like, comprising, a tank, a water-outlet in the bottom of said tank, a valve-seat in said outlet provided with a valve-disk, a guiding means in said valve-seat, a vertical stem and a valve-disk thereon, the lower portion of said stem extending down between said guiding means, a pull device for raising said stem, a bracket provided with an opening in which the upper and portion of said stem is movably arranged, spring clamping-fingers extending from said bracket, an enlargement on said stem adapted to be brought in holding engagement with said fingers for holding said stem in its raised position while the level of the water is being lowered, and means actuated by the receding water for releasing said stem from its raised position to close the said water-outlet, consisting, of a projection extending from the side of said stem, and a float and float-arm adapted to be brought in engagement with said projection, and a water-inlet valve connected with said tank, the valve being connected with and operated by the said float-arm, substantially as and for the purposes set forth.

10. In a flushing apparatus or the like, the combination, with a tank, a water-outlet, provided with a valve-seat, a vertical stem and a valve-disk thereon movably arranged above said valve-seat, a pull device for raising said stem, a clamping device for holding said stem in its raised position while the level of the water is being lowered, of a water-inlet valve arranged in the upper portion of said tank above the level of the water therein, comprising, a tubular casing, having a valve-chamber and a valve-seat, a plunger in said casing, a valve-plug connected with said plunger, an outlet-pipe connected with said casing, and means for causing a reciprocatory motion of said plunger and valve-plug, said float-arm being adapted to be brought in engagement with a portion of said vertical stem

to release said stem from its raised position with said clamping device, substantially as and for the purposes set forth.

11. In a flushing apparatus or the like, the combination, with a tank, a water-outlet, provided with a valve-seat, a vertical stem and a valve-disk thereon movably arranged above said valve-seat, a pull device for raising said stem, a clamping device for holding said stem in its raised position while the level of the water is being lowered, of a water-inlet valve arranged in the upper portion of said tank above the level of the water therein, comprising, a tubular casing, having a valve-chamber and a valve-seat, a plunger in said casing, said plunger having a slotted end portion, a valve-plug connected with the opposite end of said plunger, an outlet-pipe connected with said casing, a float and a float-arm pivotally connected with said valve-seat, and means on said float-arm extending into the slotted end portion of said plunger for causing a reciprocatory motion of the said plunger and valve-plug, said float-arm being adapted to be brought in engagement with a portion of said vertical stem to release said stem from its raised position with said clamping device, substantially as and for the purposes set forth.

12. In a flushing apparatus or the like, the combination, with a tank, a water-outlet, provided with a valve-seat, a vertical stem and a valve-disk thereon movably arranged above said valve-seat, a pull device for raising said stem, a clamping device for holding said stem in its raised position while the level of the water is being lowered, of a water-inlet valve arranged in the upper portion of said tank above the level of the water therein, comprising, a tubular casing, having a valve-chamber and a valve-seat, a plunger in said casing, said plunger having a slotted end portion, a valve-plug connected with the opposite end of said plunger, an outlet-pipe connected with said casing, a pair of perforated discs on said valve-seat, arranged near the slotted end portion of said plunger, a pivotal pin in said casing, a float and a float-arm, an eye portion connected with said float-arm and pivotally arranged on said pivotal pin, and a finger on said eye portion extending into the slotted end portion of said plunger for causing a reciprocatory motion of said plunger and valve-plug, said float-arm being adapted to be brought in engagement with a portion of said vertical stem to release said stem from its raised position with said clamping device, substantially as and for the purposes set forth.

701,549. APPARATUS FOR SHAPING METAL RECTANGLES.
MARK L. DUNN, New York, N. Y., assignor to Standard Oil Company, Bayonne, N. J., a Corporation of New Jersey. Filed Jan. 11, 1902.
Serial No. 87,714. (No model.)

Claim.—1. In an apparatus for shaping hollow metal articles, the combination with suitable fluid-pressure-applying means, of a mold having a movable wall, and means whereby the wall of the mold may be moved during the shaping operation in order to enlarge the mold and thereafter returned to its original position after the shaping operation is completed, substantially as described.

2. In an apparatus for shaping hollow metal articles the combination with a suitable fluid-pressure-applying means, of a mold comprising a movable head and wall, means whereby the wall of the mold may be moved during the shaping operation in order to enlarge the mold and thereafter returned to its original position after the shaping operation is completed, and means for moving the head, substantially as described.

3. In an apparatus for shaping hollow metal articles the combination with a suitable fluid-pressure-applying means, of a cylindrical mold having a movable wall, and means whereby the wall of the mold may be moved during the shaping operation in order to enlarge the mold and

thereafter returned to its original position after the shaping operation is completed, substantially as described.

4. In an apparatus for shaping hollow metal articles the combination with a suitable fluid-pressure-applying means, of a cylindrical mold having a movable head and wall, means whereby the wall of the mold may be moved during the shaping operation in order to enlarge the mold and thereafter returned to its original position after the shaping operation is completed, and means for moving the head, substantially as described.

5. In an apparatus for shaping hollow metal articles, the combination with a suitable fluid-pressure-applying means, of a mold having a wall made up of movable sections, and means whereby said sections may be moved during the shaping operation in order to enlarge the mold and thereafter returned to their original position after the shaping operation is completed, substantially as described.

6. In an apparatus for shaping hollow metal articles, the combination with a suitable fluid-pressure-applying means, of a mold having a wall made up of movable sections and a movable head, means whereby said sections may be moved during the shaping operation in order to enlarge the mold and thereafter returned to their original position after the shaping operation is completed, and means for giving the head an inward movement, substantially as described.

7. In an apparatus for shaping hollow metal articles, the combination with a suitable fluid-pressure-applying means, of a cylindrical mold having a wall made up of movable sections, and means whereby said sections may be moved during the shaping operation in order to enlarge the mold and thereafter returned to their original position after the shaping operation is completed, substantially as described.

8. In an apparatus for shaping hollow metal articles, the combination with a suitable fluid-pressure-applying means, of a cylindrical mold having a wall made up of movable sections and a movable head, means whereby said sections may be moved during the shaping operation in order to enlarge the mold and thereafter returned to their original position after the shaping operation is completed, and means for giving the head an inward movement, substantially as described.

9. In an apparatus for shaping hollow metal articles, the combination with a suitable fluid-pressure-applying means, of a mold composed of movable sections each section comprising a plurality of parts, and means whereby said sections may be moved during the shaping operation in order to enlarge the mold and thereafter returned to their original position after the shaping operation is completed, substantially as described.

10. In an apparatus for shaping hollow metal articles, the combination with a suitable fluid-pressure-applying means, of a mold composed of movable sections each section comprising a plurality of parts, said mold also having a movable head, means whereby said sections may be moved during the shaping operation in order to enlarge the mold and thereafter returned to their original position after the shaping operation is completed, and means for giving the head an inward movement, substantially as described.

11. A mold for use in a fluid-pressure shaping apparatus comprising a plurality of sections each section being made up of a plurality of movable parts, and means for moving the adjacent parts of each section simultaneously to enlarge the mold, substantially as described.

12. In an apparatus for shaping hollow metal articles, the combination with suitable fluid-pressure-applying means, of a mold having a wall made up of movable sections each section being composed of a plurality of parts, and means for giving the adjacent parts of each section a simultaneous movement to enlarge the mold, substantially as described.

13. In an apparatus for shaping hollow metal articles, the combination with suitable fluid-pressure-applying means, of a mold having a movable head and a wall made up of movable sections each section being composed of a plurality of parts, and means for giving the adjacent parts of each section a simultaneous movement to enlarge the mold, substantially as described.

14. In an apparatus for shaping hollow metal articles, the combination with suitable fluid-pressure-applying means, of a mold having a wall made up of movable sections, and means for giving a simultaneous movement in all the sections to enlarge the mold, substantially as described.

15. In an apparatus for shaping hollow metal articles, the combination with suitable fluid-pressure-applying means, of a mold having a movable head and a wall made up of movable sections, and means for giving a simultaneous movement to all the sections to enlarge the mold, substantially as described.

16. In an apparatus for shaping hollow metal articles, the combination with a suitable fluid-pressure-applying means, of a mold said mold having a wall composed of a plurality of movable sections each section consisting of a plurality of movable parts, and means for simultaneously moving the parts of all the sections to enlarge the mold, substantially as described.

17. In an apparatus for shaping hollow metal articles, the combination with a suitable fluid-pressure-applying means, of a mold having a mov-

able head and a wall composed of a plurality of movable sections each section consisting of a plurality of movable parts, and means for simultaneously moving the parts of all the sections to enlarge the mold, substantially as described.

18. In an apparatus for shaping hollow metal articles, the combination with suitable fluid-pressure-applying means, of a mold having a wall made up of sections each section comprising a plurality of movable parts, and means for moving said parts to enlarge the mold, said moving means being connected to the adjacent parts of each section, substantially as described.

19. In an apparatus for shaping hollow metal articles, the combination with suitable fluid-pressure-applying means, of a mold having a movable head and a wall made up of sections each section comprising a plurality of movable parts, and means for moving said parts to enlarge the mold, said moving means being connected to the adjacent parts of each section, substantially as described.

20. In an apparatus for shaping hollow metal articles, the combination with a plurality of supports, of a plurality of movable mold-sections carried by the supports, means whereby the supports are permitted to have a relative movement with respect to each other to open and close the mold, and means for moving the sections to enlarge the mold as the shaping operation proceeds, substantially as described.

21. In an apparatus for shaping hollow metal articles, the combination with a plurality of supports, of a plurality of movable mold-sections carried by the supports, means whereby the supports are permitted to have a relative movement with respect to each other to open and close the mold, means for moving the sections to enlarge the mold as the shaping operation proceeds, and a movable head cooperating with the mold-sections, substantially as described.

22. In an apparatus for shaping hollow metal articles, the combination with a plurality of supports, of a plurality of movable mold-sections carried by the supports, means whereby the supports are permitted to have a relative movement with respect to each other to open and close the mold, and means carried by the supports for moving the sections to enlarge the mold as the shaping operation proceeds, substantially as described.

23. In an apparatus for shaping hollow metal articles, the combination with a plurality of supports, of a plurality of movable mold-sections carried by the supports, means whereby the supports are permitted to have a relative movement with respect to each other to open and close the mold, means carried by the supports for moving the sections to enlarge the mold as the shaping operation proceeds, and a movable head cooperating with the mold-sections, substantially as described.

24. In an apparatus for shaping hollow metal articles, the combination with suitable fluid-pressure-applying means, of a plurality of supports, a plurality of movable mold-sections carried by the supports, means whereby the supports are permitted to have a relative movement toward and from each other, and an abutment arranged to be moved into and out of position between the supports when they are opened in order to position and remove the articles to be shaped, substantially as described.

25. In an apparatus for shaping hollow metal articles, the combination with suitable fluid-pressure-applying means, of a plurality of supports, a plurality of movable mold-sections carried by the supports, means whereby the supports are permitted to have a relative movement toward and from each other, an abutment arranged to be moved into and out of position between the supports when they are opened in order to position and remove the articles to be shaped, and a movable head cooperating with the mold-sections, substantially as described.

26. In an apparatus for shaping hollow metal articles, the combination with suitable fluid-pressure-applying means, of a plurality of supports, a plurality of movable mold-sections carried by the supports, means whereby the supports are permitted to have a relative movement toward and from each other, an abutment arranged to be moved into and out of position between the supports when they are opened in order to position and remove the articles to be shaped, and a movable head cooperating with the mold-sections, substantially as described.

27. In an apparatus for shaping hollow metal articles, the combination with suitable fluid-pressure-applying means, of a plurality of supports, a plurality of movable mold-sections carried by the supports, means whereby the supports are permitted to have a relative movement toward and from each other, an abutment arranged to be moved into and out of position between the supports when they are opened in order to position and remove the articles to be shaped, and a movable head cooperating with the mold-sections, substantially as described.

28. In an apparatus for shaping hollow metal articles, the combination with suitable fluid-pressure-applying means, of a plurality of supports, a plurality of movable mold-sections carried by the supports, means whereby the supports are permitted to have a relative movement toward and from each other, an abutment arranged to be moved into and out of position between the supports when they are opened in order to position and remove the articles to be shaped, and a movable head cooperating with the mold-sections, substantially as described.

29. In an apparatus for shaping metal barrels, the combination with suitable fluid-pressure-applying means, of a mold, and means for increasing the diameter of the mold at its center in order to give the barrel a bilged shape and for restoring the mold to its original form after the shaping operation, substantially as described.

30. In an apparatus for shaping metal barrels, the combination with suitable fluid-pressure-applying means, of a mold, means for increasing the diameter of the mold at its center in order to give the barrel a bilged shape, suitable heads or abutments cooperating therewith, and means for causing one of the heads or abutments to move inward during the shaping operation, substantially as described.

31. In a machine for shaping metal receptacles, the combination with a plurality of supports mounted to permit a relative opening and closing movement, of a plurality of mold-sections mounted on the supports each section being composed of a plurality of parts having their adjacent ends abutting, means for giving the parts an outward movement at their line of contact, and means for subjecting the receptacle to an interior fluid-pressure, substantially as described.

32. In a machine for shaping metal receptacles, the combination with a plurality of supports mounted to permit a relative open and closing movement, of a plurality of mold-sections mounted on the supports each section being composed of a plurality of parts having their adjacent ends abutting, means for giving the parts an outward movement at their line of contact, an abutment for one end of the receptacle, a head for the other end, means for moving one of these parts during the shaping operation, and means for subjecting the interior of the receptacle to fluid-pressure, substantially as described.

33. In a machine for shaping metal receptacles, the combination with a plurality of supports mounted to permit an opening and closing movement, of a plurality of mold-sections carried by said supports, each of said sections comprising a plurality of parts the adjacent ends of which abut, an abutment cooperating with the mold-sections at one end, a head cooperating with the mold-sections at the other end, means connected to adjacent parts of each support at their line of contact for moving the parts outward, means for subjecting the interior of the receptacle to fluid-pressure, and means for moving the head inward as the parts of the mold are moved outward, substantially as described.

34. In a machine for shaping metal receptacles, the combination with a plurality of supports mounted to permit an opening and closing movement, of a plurality of mold-sections carried by said supports, each of said sections comprising a plurality of parts the adjacent ends of which abut, a plurality of rotating gears, and connections between the gears and said parts, substantially as described.

35. In a machine for shaping metal receptacles, the combination with a plurality of supports mounted to permit an opening and closing movement, of a plurality of mold-sections carried by said supports, each of said sections comprising a plurality of parts the adjacent ends of which abut, a plurality of rotating gears, connections between the gears and said parts, a head, and means for moving the head inward as the parts are moved outward, substantially as described.

36. The combination with a plurality of supports mounted to permit an opening and closing movement, of means for locking the supports in their closed position, a plurality of mold-sections carried by the supports, an abutment cooperating with the mold-sections at one end, means for moving the mold-sections outward at the center, means for subjecting the interior of the receptacle to fluid-pressure, substantially as described.

37. The combination with a plurality of supports mounted to permit an opening and closing movement, of means for locking the supports in their closed position, a plurality of mold-sections carried by the supports, an abutment cooperating with the mold-sections at one end, means for moving the mold-sections outward at the center, means for subjecting the interior of the receptacle to fluid-pressure, a head, and means for moving the head inward as the parts of the mold are moved outward, substantially as described.

38. In a machine for shaping metal receptacles, the combination with a plurality of bilged supports, said supports being mounted to have a relative opening and closing movement, of means for locking the supports in their closed position, an abutment, a series of mold-sections carried by the supports, each section being composed of a plurality of parts, means for giving the parts of said sections an outward movement, and means for subjecting the interior of the receptacle to fluid-pressure, substantially as described.

39. In a machine for shaping metal receptacles, the combination with a plurality of bilged supports, said supports being mounted to have a relative opening and closing movement, of means for locking the supports in their closed position, an abutment, a series of mold-sections carried by the supports, each section being composed of a plurality of parts, means for giving the parts of said sections an outward movement, means for subjecting the interior of the receptacle to fluid-pressure, a head, and means

for moving the head inward during the shaping operation, substantially as described.

40. In a machine for shaping metal receptacles, the combination with a plurality of bilged supports, said supports being mounted to have a relative opening and closing movement, of means for locking the supports in their closed position, an abutment, a series of mold-sections carried by the supports, each section being composed of a plurality of parts, means for giving the sections a simultaneous outward movement, and means for subjecting the interior of the receptacle to fluid-pressure, substantially as described.

41. In a machine for shaping metal receptacles, the combination with a plurality of bilged supports, said supports being mounted to have a relative opening and closing movement, of means for locking the supports in their closed position, an abutment, a series of mold-sections carried by the supports, each section being composed of a plurality of parts, means for giving the sections a simultaneous outward movement, means for subjecting the interior of the receptacle to fluid-pressure, a head, and means for moving the head inward during the shaping operation, substantially as described.

42. In a machine for shaping metal receptacles, the combination with a plurality of bilged supports mounted to permit an opening and closing movement, of an abutment, a plurality of mold-sections carried by the supports, each of said mold-sections consisting of a plurality of parts, means for locking the supports in closed position, a plurality of gears, connections between said gears and adjacent parts of the sections, means for rotating the gears, means for moving the parts of the sections to give the mold a bilged form, and means for producing an interior fluid-pressure, substantially as described.

43. In a machine for shaping metal receptacles, the combination with a plurality of bilged supports mounted to permit an opening and closing movement, of an abutment, a plurality of mold-sections carried by the supports, each of said mold-sections consisting of a plurality of parts, means for locking the supports in closed position, a plurality of gears, connections between said gears and adjacent parts of the sections, means for rotating the gears, means for moving the parts of the sections to give the mold a bilged form, means for producing an interior fluid-pressure, a head, and means for moving said head inward, substantially as described.
